# Document A: Research Report

## 1. Conceptual Foundations of Market Sentiment Measurement

### 1.1 Defining Market Emotion

The measurement of market sentiment through quantitative indices represents one of the most significant developments in behavioral finance, transforming abstract psychological concepts into actionable investment tools. At its core, the greed and fear index operationalizes the observation that financial markets are not purely efficient mechanisms for price discovery but are instead profoundly influenced by collective human emotion. This understanding has profound implications for how investors interpret market movements, assess risk, and identify opportunities that arise when market psychology becomes disconnected from fundamental values (finhacker.cz) .

The theoretical foundation for sentiment measurement rests on decades of research in behavioral economics, which has systematically documented how cognitive biases and emotional responses cause systematic deviations from rational expectations. Investors do not simply process information objectively; rather, they filter data through psychological lenses that amplify certain signals while suppressing others. During periods of market stress, **loss aversion** causes investors to overweight negative information, leading to panic selling that drives prices below fundamental values. Conversely, during bull markets, **overconfidence** and **herding behavior** create self-reinforcing cycles of optimism that push valuations to unsustainable levels (greedfearindex.com) .

The greed and fear index attempts to capture these emotional extremes through a composite metric that aggregates multiple market-based indicators. Unlike survey-based sentiment measures that rely on self-reported opinions, market-based indices derive their signals from actual investor behavior—how market participants deploy capital, hedge risk, and position for future outcomes. This behavioral approach offers several advantages: it is **objective**, **continuously updated**, and **directly tied to financial consequences** rather than stated preferences (Alternative.me) .

**1.1.1 Greed as a Market Driver** Greed in financial markets manifests as excessive optimism, risk-taking behavior, and the collective pursuit of returns beyond what fundamentals would justify. This emotional state typically emerges during prolonged bull markets when rising prices create self-reinforcing feedback loops of confidence and speculative behavior. The psychological mechanisms underlying market greed include **recency bias** (overweighting recent positive returns), **confirmation bias** (seeking information that validates bullish views), and **fear of missing out (FOMO)** (where the pain of watching others profit exceeds the fear of potential losses) (whaleportal.com) .

From a market structure perspective, greedy periods are characterized by several observable phenomena: **expanding valuation multiples** as discount rates compress, **increased leverage utilization** with margin debt expanding rapidly, **narrowing credit spreads** as investors reach for yield with inadequate risk compensation, **elevated IPO and M&A activity** as companies capitalize on favorable conditions, and **reduced demand for portfolio insurance** through options. These indicators collectively signal

that investors are discounting risk and prioritizing return capture above capital preservation (Investopedia) .

The quantitative detection of greed requires identifying market variables that capture these behavioral manifestations. **Price momentum** that significantly exceeds historical norms suggests extrapolative expectations. The **ratio of stocks making new highs versus new lows** indicates the breadth of optimistic sentiment. **Compressed volatility expectations**, as reflected in options pricing, reveal complacency about downside risk. When these indicators align simultaneously, they create high-confidence signals that greed has reached unsustainable extremes, historically preceding significant market corrections (SoFi) .

Historical episodes of extreme greed include the **dot-com bubble of 1999-2000**, when technology stock valuations reached unprecedented levels relative to earnings; the **pre-financial crisis period of 2006-2007**, when credit spreads compressed to historically tight levels despite deteriorating underlying credit quality; and various **cryptocurrency manias** where speculative enthusiasm drove digital asset prices to extreme valuations. In each case, sentiment indicators would have registered extreme greed readings, potentially alerting contrarian investors to impending market corrections (Alden Investment Group) .

**1.1.2 Fear as a Market Driver** Fear represents the mirror image of greed in market psychology, driving excessive risk aversion, panic selling, and asset undervaluation that create opportunities for disciplined long-term investors. This emotional state typically emerges rapidly following negative catalysts —economic shocks, geopolitical events, or financial system stress—but can also develop gradually during extended bear markets as negative returns compound investor pessimism. The psychological impact of fear is often more intense and rapid than greed, reflecting the **asymmetric nature of human emotional responses to gains versus losses** (Investopedia) .

Measurable manifestations of market fear include: **volatility expansion** as investors demand greater compensation for bearing equity risk, with implied volatility often exceeding realized volatility by substantial margins; **flight-to-quality flows** that drive down government bond yields while widening credit spreads as investors discriminate sharply between safe and risky assets; **defensive sector outperformance** as market participants prioritize capital preservation over growth exposure; and **liquidity deterioration** as market makers become less willing to commit capital, amplifying price movements in both directions (Source) .

The measurement of fear focuses on indicators of risk aversion and defensive positioning. **Elevated put/call ratios** indicate demand for downside protection. **Expanding credit spreads** reveal risk aversion in fixed income markets. **Negative price momentum** that exceeds historical norms suggests panic selling. **Safe haven assets** such as precious metals and government bonds may exhibit anomalous strength relative to risk assets. When multiple fear indicators reach extreme levels simultaneously, the composite sentiment index signals potential opportunity for contrarian investors (Source) .

The **2008 financial crisis** provides the most dramatic modern example of fear-driven market behavior, with volatility measures reaching unprecedented levels and credit markets experiencing systemic stress. This extreme period coincided with widespread deleveraging, forced liquidations, and a complete collapse in risk appetite that persisted for months. The persistence of elevated fear measures even after substantial market declines illustrates how **recent losses create disproportionate emotional impact**, leading to continued defensive positioning beyond what fundamental valuation would suggest (MacroMicro) .

**1.1.3 The Cyclical Nature of Investor Psychology** The alternation between greed and fear follows remarkably consistent patterns across market cycles, suggesting **deep-seated psychological mecha-**

**nisms that transcend specific historical circumstances**. This cyclicality emerges from the interaction of performance feedback, social influence, and adaptive learning in investor populations. As markets rise, successful investors attract followers and capital, amplifying trends through positive feedback. Eventually, trend exhaustion and unexpected shocks trigger reversal, with the same feedback mechanisms operating in reverse during declines (ResearchGate) .

The psychological cycle typically progresses through identifiable phases: **optimism builds** during early recovery periods, progressing to **excitement** and eventually **euphoria** as gains accelerate; the peak of euphoria gives way to **anxiety** as early signs of deterioration emerge, followed by **denial**, **panic**, and finally **capitulation** at maximum pessimism; the cycle then begins anew as conditions stabilize and gradual recovery restores confidence. While the specific timing and amplitude of each phase varies considerably, the sequential structure remains remarkably consistent (MacroMicro 財經 M 平方) .

Quantitative sentiment indices attempt to capture cyclical positioning through **normalization procedures that compare current readings to historical distributions**. A greed index reading of 75 may indicate extreme optimism in a historical context, but whether this signals imminent reversal depends on whether the underlying cycle is mature or still developing. This temporal dimension complicates simple threshold-based strategies and motivates more sophisticated approaches that incorporate trend and momentum in sentiment itself (A1 Trading Company) .

### 1.2 Historical Context of Sentiment Indicators

**1.2.1 Early Behavioral Finance Research** The intellectual foundations of sentiment measurement trace to pioneering researchers who challenged the efficient market hypothesis with evidence of systematic behavioral biases. **Charles Mackay's 1841 study of market manias**, while pre-dating formal academic finance, documented recurring patterns of speculative excess. More systematically, **Graham and Dodd's 1934 Security Analysis** emphasized psychological factors in market fluctuations, advocating disciplined approaches that explicitly countered emotional decision-making (Investopedia) .

The modern behavioral finance revolution began in the 1970s and 1980s with experimental and empirical studies documenting specific deviations from rational expectations. **Kahneman and Tversky's prospect theory** (1979) provided a formal framework for understanding loss aversion and probability weighting that explained observed investment behaviors. **Robert Shiller's work on excess volatility** demonstrated that stock price movements could not be fully explained by rational forecasts of future dividends, implying an important role for sentiment-driven speculation (Source) .

These theoretical advances motivated quantitative sentiment measures. Early efforts focused on **survey-based indicators**, such as the **American Association of Individual Investors (AAII) sentiment survey** initiated in 1987, which aggregated self-reported bullish and bearish views. While valuable, these measures suffered from **sampling limitations, response lag, and susceptibility to manipulation** (Source) .

**1.2.2 Evolution of Quantitative Sentiment Metrics** The 1990s and 2000s witnessed rapid development of **market-based sentiment indicators** that addressed survey limitations. The **VIX index**, introduced by the Chicago Board Options Exchange in 1993, provided a real-time measure of implied volatility from S&P 500 options prices. Often termed the "fear gauge," the VIX captured market expectations of near-term volatility that typically spike during market stress periods (supertype.ai) .

Parallel developments expanded the sentiment toolkit. The **put/call ratio** emerged as a measure of options market positioning. **Advance-decline lines** and **new highs-new lows indicators** captured

market breadth dimensions obscured by aggregate price indices. **Credit spread measures** revealed risk appetite in fixed income markets. The integration of these diverse indicators into **composite sentiment indices** represented a major methodological advance, enabling more robust sentiment assessment through cross-validation and noise reduction (Source) .

The proliferation of **alternative data sources** in the 2010s—including social media sentiment, search trend data, and satellite imagery—further expanded possibilities. Natural language processing techniques enabled systematic extraction of sentiment from unstructured text. However, these novel sources also introduced challenges around **data quality, sample representativeness, and signal decay** that require careful validation (Source) .

**1.2.3 Modern Applications Across Asset Classes** Contemporary sentiment measurement has expanded far beyond equity markets to encompass **virtually all traded asset classes**. Cryptocurrency markets have proven particularly fertile for sentiment analysis given extreme volatility and retail participation. The **Crypto Fear & Greed Index** developed by Alternative.me adapts composite approaches to digital assets, combining volatility, momentum, social media sentiment, and market dominance metrics (Cheddar Flow) .

Fixed income markets employ **yield curve positioning, credit spread dynamics, and flow data** as sentiment proxies. Currency markets use **futures positioning, options risk reversals, and safe-haven flow patterns**. Commodity markets analyze **inventory levels, curve shapes, and speculative positioning**. The common thread is recognition that **market prices incorporate both fundamental information and behavioral distortions** that can be quantified and potentially exploited (Source) .

### 1.3 Theoretical Framework

**1.3.1 Efficient Market Hypothesis vs. Behavioral Finance** The efficient market hypothesis (EMH) posits that asset prices fully reflect all available information, making consistent outperformance through any analytical approach—including sentiment analysis—impossible in equilibrium. **Behavioral finance challenges this view** by identifying **limits to arbitrage** that allow sentiment-driven mispricing to persist: **fundamental risk** (uncertainty about true values), **noise trader risk** (sentiment may intensify before reversing), and **implementation costs** (short-selling constraints, transaction costs) (Axiory Global) .

The reconciliation recognizes that markets are **approximately efficient in the long run but exhibit predictable short-term deviations** when behavioral forces are strong and arbitrage is constrained. Sentiment indices are most valuable precisely during these **inefficiency periods**, providing discipline against emotional crowd behavior when it is most extreme and most costly to follow (itez.com) .

**1.3.2 Herd Behavior and Market Extremes** **Herd behavior**—the tendency to follow collective actions rather than private information—amplifies sentiment cycles and produces extremes that indices measure. **Informational cascades** occur when observers rationally infer information from others' actions. **Reputational herding** creates incentives for investment professionals to avoid deviating from consensus. **Social influence** spreads narratives and emotional states through communication networks (Source) .

Herd behavior produces distinctive patterns: **momentum in returns** as price changes attract trend-following flows; **volatility clustering** as sentiment self-reinforces; and **bubble formation** when feedback between prices and sentiment becomes decoupled from fundamentals. Sentiment indices identify

when herding has reached **unsustainable extremes** where reversal becomes increasingly probable (yahoo.com) .

**1.3.3 Contrarian Investment Principles** **Contrarian investment**—systematically opposing crowd behavior at sentiment extremes—represents the primary practical application of sentiment measurement. The theoretical justification rests on **exhaustion of buying/selling power at extremes**: when nearly all market participants have adopted the same view, the pool of potential new adherents is exhausted, and even small contrary information can trigger large position unwinds (Public.com) .

Successful contrarian implementation requires **discipline to act against prevailing sentiment and patience to wait for extremes to develop and correct**. Sentiment indices provide **quantitative discipline** for this process, identifying specific threshold levels that indicate potentially attractive entry and exit points. However, **timing remains uncertain**, as markets can remain in extreme states for extended periods, and **risk management is essential** to survive adverse extensions (Source) .

## 2. Core Components of a Greed and Fear Index

### 2.1 Market Momentum Indicators

**2.1.1 Price Rate of Change Metrics** The **rate of change (ROC)** measures percentage price change over specified lookback periods, providing normalized momentum assessment. For broad market indices, the **125-day ROC** (approximately six months) serves as standard benchmark, capturing medium-term trend strength while filtering short-term noise (Indeed) .

The calculation is: **ROC_t = (P_t - P_{t-n}) / P_{t-n} × 100**. Positive values indicate upward momentum (greed); negative values indicate downward momentum (fear). Normalization to 0-100 sentiment scale employs **percentile ranking against historical distribution** or direct scaling against predefined boundaries. The interpretation requires market context—strong momentum during economic expansion may reflect justified optimism rather than excessive greed (Investopedia) .

**2.1.2 Moving Average Deviations** **Moving average deviation** measures current price position relative to trend, identifying extended conditions. The **percentage distance from 125-day SMA** is standard: **Deviation_t = (P_t - SMA_n,t) / SMA_n,t × 100**. Large positive deviations suggest overbought, greed-dominated conditions; large negative deviations indicate oversold, fear-dominated conditions (ForexBee) .

This approach offers advantages over raw ROC by **incorporating trend direction**—prices above rising trends are less extended than identical levels above falling trends. The smoothing properties introduce intentional lag that reduces noise but may delay turning point identification. The **125-day period represents common compromise**, though sophisticated implementations may employ multiple horizons or adaptive smoothing (finhacker.cz) .

**2.1.3 Index-Level Momentum Calculation** For broad market sentiment, momentum calculation focuses on major benchmarks like the **S&P 500**, given comprehensive coverage and liquid derivatives markets. **Daily closing prices** provide standard frequency, with **total-return indices** preferred for more comprehensive measurement. Implementation requires handling **corporate actions, index composition changes, and market holidays** (Alternative.me) .

Normalization approaches include **percentile ranking** (adaptive to changing conditions but requiring extensive history) or **direct scaling against fixed boundaries** (more stable but may saturate during

extremes). Hybrid approaches employ **adaptive boundaries based on rolling historical percentiles** to balance stability and responsiveness (Investopedia) .

### 2.2 Market Strength Indicators

**2.2.1 52-Week Highs vs. Lows Ratio** The **new highs/new lows ratio** directly measures market leadership breadth. High ratios indicate broad-based optimism; low ratios suggest widespread weakness even if cap-weighted indices show resilience. Calculation: **Ratio_t = NewHighs_t / (NewHighs_t + NewLows_t) × 100** (A1 Trading Company) .

**Deteriorating ratios during index advances**—fewer stocks making new highs despite higher index levels—represent classic bearish divergence indicating narrowing leadership and vulnerability. Conversely, improving ratios during declines suggest underlying accumulation and potential bottoming. Normalization requires **handling asymmetric distributions**, with logarithmic transformation or percentile-based approaches commonly employed (MacroMicro) .

**2.2.2 Stocks Above Key Moving Averages** The **percentage of stocks above 200-day moving averages** provides alternative strength measurement with different sensitivity characteristics. Calculation: **%Above_t = Count(P_i,t > SMA_200,i,t) / N × 100**. Values above **80%** indicate broad strength consistent with greed; below **20%** indicates broad weakness consistent with fear (MacroMicro) .

The **200-day period** represents standard convention, though **50-day measures** may be employed for more responsive signals. Multiple horizons can be combined to capture both short-term participation and longer-term trend alignment. Threshold levels should be **validated against historical data** as different regimes exhibit systematically different participation patterns (LPL Financial) .

**2.2.3 Advance-Decline Line Analysis** The **advance-decline line** cumulates daily net advances (advancers minus decliners) to create running total reflecting participation trends. **Divergences between advance-decline line and price indices** indicate weakening or strengthening breadth that may presage trend changes (Source) .

For sentiment indices, **rate of change or position relative to trend** may be more informative than absolute level. The **McClellan Oscillator** (19-day minus 39-day EMA of net advances) and **Summation Index** (cumulative oscillator) provide sophisticated derivatives with specific cycle sensitivities. These require **normalization procedures** given unbounded nature of cumulative values (Sanbase) .

### 2.3 Market Breadth Indicators

**2.3.1 Volume-Weighted Advance-Decline Metrics** **Volume-weighted breadth** incorporates trading activity to assess conviction behind price movements. The basic calculation sums volume in advancing versus declining stocks: **VWAD_t = Σ(Volume_i,t × I[Price_i,t > Price_i,t-1]) / Σ(Volume_i,t × I[Price_i,t < Price_i,t-1])**. High up-volume ratios indicate greed-driven accumulation; high down-volume ratios indicate fear-driven distribution (Source) .

**Divergences where price breadth improves but volume breadth deteriorates** suggest weakening conviction that may limit advance sustainability. Conversely, strong volume breadth during price consolidation may indicate accumulation and pending breakout. The **McClellan Volume Summation Index** applies exponential smoothing to volume-weighted net advances for longer-term perspective (Source) .

**2.3.2 New Highs/New Lows Differential** The **differential between new highs and new lows**, scaled by total issues, creates normalized breadth measure: **Diff_t = (NewHighs_t - NewLows_t) / TotalIssues_t × 100**. This addresses limitations of raw counts that grow mechanically with market size (yahoo.com) .

The differential format emphasizes **net balance of strength versus weakness** rather than absolute levels. Large positive values indicate widespread breakout behavior (greed); large negative values indicate pervasive breakdown (fear). Rapid differential swings during transitions may provide **early indication of sentiment regime change** before price indices fully reflect shifts (Personal Finance & Money Stack Exchange) .

**2.3.3 McClellan Oscillator Applications** The **McClellan Oscillator** (19-day EMA minus 39-day EMA of net advances) creates bounded oscillator with typical range of **±100**, extreme readings beyond **±150** indicating unusual breadth conditions. The **Summation Index** (cumulative oscillator) provides longer-term breadth measure (supertype.ai) .

For sentiment indices, these measures are **normalized to 0-100 scale** based on historical extremes. The oscillator's **mean-reverting properties** make it particularly useful for identifying sentiment extremes likely to reverse. However, **calculation complexity and data requirements** may exceed resources for simpler implementations (presidiowp.com) .

### 2.4 Volatility Measures

**2.4.1 VIX Index Interpretation** The **CBOE Volatility Index (VIX)** measures implied volatility from S&P 500 options prices, reflecting **30-day forward volatility expectations**. The VIX exhibits **strong inverse correlation with equity returns**, spiking during stress and declining during calm advances (realtrading.com) .

For sentiment construction, **raw VIX levels require normalization** given significant variation in typical ranges across regimes. Superior approaches **compare VIX to its historical distribution** (percentile ranking) or **recent trend** (deviation from 50-day MA). The standard approach uses **50-day moving average comparison**, with significant positive deviation indicating fear and negative deviation indicating greed (chartswatcher.com) .

**2.4.2 Realized vs. Implied Volatility** The **realized-implied volatility comparison** provides additional sentiment information. When **implied volatility substantially exceeds realized**, options markets price elevated uncertainty not yet materialized, suggesting fear premium. When **implied falls below realized**, complacency may indicate underpricing of risk (MacroMicro) .

The **volatility risk premium**—systematic excess of implied over realized—represents compensation for selling volatility protection. Average implied typically exceeds realized by **2-4 volatility points**, so sentiment measures should assess **deviations from this baseline** rather than absolute differences (CapTrader) .

**2.4.3 Volatility Term Structure Analysis** The **VIX term structure**—implied volatility across maturities—provides information about expected uncertainty duration. **Upward-sloping term structure** (long-dated > short-dated) indicates normal conditions with expected mean reversion. **Inverted or flat term structure** suggests elevated near-term uncertainty, typically associated with stress periods (LinkedIn) .

Slope measurement as **3-month minus 1-month implied vol difference** with extreme negative values indicating fear. However, **additional data requirements and calculation complexity** may reserve term structure components for advanced implementations, with simpler indices relying on spot VIX and trend (Axiory Global) .

### 2.5 Options Market Sentiment

**2.5.1 Put/Call Ratio Dynamics** The **put/call ratio** compares put option volume (downside protection) to call option volume (upside speculation). **Elevated ratios indicate defensive positioning (fear)**; **depressed ratios suggest speculative optimism (greed)**. The **CBOE Total Put/Call Ratio** serves as standard benchmark, with **5-day moving average** reducing daily noise (itez.com) .

Historical analysis reveals typical range of **0.5 to 1.5**, with values **below 0.7 indicating greed** and **above 1.0 indicating fear**. Normalization inverts the ratio (higher P/C = lower sentiment) and maps extremes to scale boundaries. **Structural trends in options market usage** require adaptive normalization procedures (AlphaPoint) .

**2.5.2 Skew and Tail Risk Indicators** **Volatility skew** measures relative pricing of out-of-the-money puts versus calls. **Steep skew** indicates elevated demand for crash protection (fear); **flat or inverted skew** suggests complacency about downside risk (greed). The **SKEW index** provides standardized measurement, with values **above 130-140 indicating elevated tail risk concern** and **below 120-125 suggesting complacency** (TraderLion) .

Skew offers **information distinct from VIX level and put/call ratio**, as it can remain elevated even when VIX is moderate if investors specifically price tail risk. However, **significant noise and need for substantial smoothing** may limit reliability for standard implementations (Escalent) .

**2.5.3 Options Flow Analysis** **Options flow analysis** tracks transaction direction and size to identify institutional positioning. **Unusual call buying** may indicate accumulating greed; **put buying spikes** may indicate developing fear. Implementation requires **high-frequency transaction data** distinguishing buyer-initiated versus seller-initiated trades (Source) .

Aggregated metrics include **call/put dollar volume ratios**, **unusual volume flags** (volume $> 2\times$ average), and **net premium flow measures**. However, **data requirements and computational complexity** may exceed standard implementation resources, with flow analysis reserved for institutional-grade systems (greedfearindex.com) .

### 2.6 Fixed Income and Credit Spreads

**2.6.1 Junk Bond Yield Spreads** The **high-yield spread**—yield differential between junk bonds and comparable Treasuries—measures credit risk appetite. **Narrow spreads** indicate aggressive yield reaching with inadequate risk compensation (greed); **wide spreads** indicate risk aversion demanding substantial premia (fear) (Investopedia) .

Calculation uses **ICE BofA US High Yield Index** and matched-duration Treasuries. Historical range: **300-600 basis points** in normal conditions, **below 300 indicating unusual risk appetite**, **above 1000 indicating severe stress**. The **2008 crisis exceeded 2000 basis points**; **2021 saw sustained levels below 300**. **Logarithmic transformation or percentile ranking** addresses asymmetric distribution (Source) .

**2.6.2 Investment Grade vs. High Yield Divergence** **Relative performance of investment grade versus high-yield credit** provides additional sentiment granularity. When investors **favor investment grade despite minimal yield sacrifice**, risk aversion is elevated. When they **aggressively pursue high-yield exposure**, risk appetite is strong. This divergence may identify sentiment shifts before full manifestation in absolute spreads (Quantified Strategies) .

Calculation compares **spread changes or total returns across quality tiers**, with regression-based adjustment for duration and sector differences to isolate pure risk appetite signal. However, **additional complexity may not be justified** for standard implementations where absolute high-yield spreads provide adequate information (Source) .

**2.6.3 Credit Default Swap Implications** **Credit default swaps (CDS)** provide alternative credit risk measurement with **standardized contracts, continuous pricing, and pure credit risk exposure**. CDS indices (**CDX, iTraxx**) enable broad sentiment assessment. CDS typically **lead bond spread movements** due to superior liquidity (Source) .

The **CDS-bond basis**—difference between CDS and bond-implied spreads—reflects funding conditions and arbitrage constraints indicating market stress. However, **data access costs and analytical complexity** may reserve CDS components for institutional implementations (stockgeist.ai) .

### 2.7 Safe Haven Demand Metrics

**2.7.1 Equity-Bond Performance Differential** The **equity-bond return comparison** over **20-day periods** indicates risk appetite: **stock outperformance = greed** (risk preference); **bond outperformance = fear** (flight to quality). Calculation: **SafeHaven_t = Return_Equity,20d - Return_Bond,20d** (cookewm.com) .

Normalization requires **historical analysis of typical differential ranges**, with extreme values mapping to sentiment extremes. Consideration of **yield environment and economic conditions** improves interpretation—equity outperformance during expansion may reflect justified optimism rather than excessive greed (Source) .

**2.7.2 Precious Metals Correlation** **Gold and silver performance relative to risk assets** provides alternative safe haven measure. **Strong gold performance during equity declines** indicates fear-driven diversification; **gold underperformance during risk-on periods** suggests greed-driven neglect of safety. The **gold-equity correlation** itself provides information, with **negative correlation indicating typical safe haven behavior** (aimtechnologies.co) .

Integration offers **diversification of safe haven measurement**, reducing vulnerability to idiosyncratic factors affecting single assets. However, **gold's unique monetary and cultural role** makes it standard benchmark, with other precious metals as supplementary measures (RavenPack) .

**2.7.3 Currency Flight-to-Quality Patterns** **Currency markets exhibit flight-to-quality patterns**: demand for **USD, JPY, CHF** increases during stress; **funding currencies (AUD, NZD, emerging markets)** depreciate. These patterns reflect **direct safe haven demand and carry trade unwinding** (Semantic Visions) .

Measures include **DXY (dollar index) performance**, **JPY cross movements**, or **risk-on/risk-off currency factor returns**. Interpretation requires **awareness of interest rate differential influences**, suggesting residualization or comparison to interest rate-justified levels for pure sentiment ex-

traction. For **equity-focused indices, currency measures may receive reduced weight** (Alden Investment Group) .

## 3. Alternative Index Implementations

### 3.1 Cryptocurrency Market Applications

Cryptocurrency markets exhibit **24/7 trading, extreme volatility, strong retail participation, and rich on-chain data**—characteristics requiring adapted sentiment approaches. The **Crypto Fear & Greed Index** by Alternative.me exemplifies successful adaptation (MarketWatch) .

#### 3.1.1 Crypto Fear & Greed Index Methodology

| Component | Weight | Description |
|---|---|---|
| **Volatility** | 25% | Current BTC volatility and max drawdown vs. 30/90-day averages |
| **Market Momentum/Volume** | 25% | Current volume and momentum vs. 30/90-day averages |
| **Social Media** | 15% | Twitter hashtag analysis and engagement rates |
| **Surveys** | 15% | Weekly crypto polls (currently paused) |
| **Bitcoin Dominance** | 10% | BTC market cap share vs. historical range |
| **Google Trends** | 10% | Search volume for Bitcoin-related queries |

*Table 1: Crypto Fear & Greed Index Component Structure*

This structure reflects **crypto-specific characteristics**: heavy weighting of volatility and momentum acknowledges technical, trend-following nature; **social media integration** recognizes narrative importance; **Bitcoin dominance** captures unique market structure with no traditional equivalent (Wilmington Trust) .

**3.1.2 Volatility-Adjusted Bitcoin Metrics** The **volatility component** compares current Bitcoin volatility and maximum drawdown to **30-day and 90-day averages**. **Elevated volatility indicates fear; suppressed volatility indicates greed**. This **relative approach** is essential given crypto's evolving baseline volatility (altindex.com) .

**Maximum drawdown** supplements standard volatility by capturing **peak-to-trough decline magnitude** that pure volatility measures may miss. Large drawdowns relative to historical experience indicate unusual stress, even if absolute price levels remain elevated (supertype.ai) .

**3.1.3 Social Media Sentiment Integration** **Social media analysis** uses **natural language processing of Twitter posts** for cryptocurrency-related hashtags and mentions. The algorithm analyzes **post volume and engagement speed** to determine information spread velocity. **High interaction rates indicate greedy sentiment** (growing public interest, potential FOMO); **low or negative engagement indicates fear** (Source) .

Challenges include **bot detection, coordinated manipulation, and sentiment classification accuracy**. Robust implementations employ **multiple filtering layers and cross-validation against price movements** (heygotrade.com) .

**3.1.4 Market Momentum and Volume Analysis** The **momentum/volume component** compares current activity to **30/90-day averages**. **High buying volume in rising markets indicates greed**; **high selling volume in declining markets indicates fear**. Volume provides **essential confirmation of price signals** that might otherwise reflect manipulation or low-liquidity artifacts (Axiory Global) .

**Exchange selection and data quality** are critical given fragmentation across venues with varying reliability. Reputable volume aggregation and **wash trading detection** ensure measured volume reflects genuine participation (Source) .

**3.1.5 Dominance and Trends Components** **Bitcoin dominance**—BTC's share of total crypto market capitalization—serves as **unique crypto-specific sentiment indicator**. **Rising dominance indicates fear** (retreat to established cryptocurrency); **falling dominance indicates greed** (speculation in smaller altcoins). This parallels **flight-to-quality behavior in traditional markets** (MacroMicro) .

**Google Trends data** captures **retail search interest** that often precedes price movements. Strong search interest may indicate growing public attention and potential FOMO; declining interest may signal waning enthusiasm. Specific query selection significantly impacts indicator properties (ScienceDirect) .

### 3.2 Emerging Market Adaptations

Emerging market sentiment measurement requires adaptation for **data availability constraints, different market structures, and unique local factors**. The **Indonesian stock market case study** illustrates these challenges and solutions (Personal Finance & Money Stack Exchange) .

**3.2.1 Indonesia Stock Market Case Study** The Indonesian implementation faced **critical data limitations**: **put/call ratios unavailable** due to insufficient options trading volume. The solution involved **component substitution and methodological innovation** (Quantified Strategies) .

| Category | Components |
|---|---|
| **Direct Indicators** | Market momentum (IDX Composite), stock price strength (new highs/lows), volatility, volume breadth, safe haven demand (equity-bond balance) |
| **Indirect Indicators** | Exchange rate (IDR/USD), interest rate (Bank Indonesia policy rate), Buffett Indicator (market cap/GDP) |

*Table 2: Indonesian Fear and Greed Index Components*

**Macroeconomic indicator inclusion** reflects greater importance of external economic influences in emerging markets. **Currency stability, monetary policy, and overall market valuation relative to economic output** provide essential context for interpreting stock market sentiment (itez.com) .

**3.2.2 Localized Data Source Integration** Data integration required **identification of local sources**: IDX Composite prices, individual stock data, trading volumes, government bond yields from **Indonesian exchange and regulatory sources**; exchange rates, interest rates, GDP from **central bank and statistical agency publications** (Young Platform Academy) .

Challenges included **harmonizing different frequencies, formats, and quality standards**. Price and volume data required minimal processing; **macroeconomic indicators with publication lags required interpolation and nowcasting** for daily sentiment updates. **Functional programming approach** with modular indicator calculation functions facilitated testing and modification (GreenBook) .

**3.2.3 Regional Volatility Adjustments** Emerging market **higher baseline volatility** requires adapted normalization. The Indonesian implementation employed **percentage-based scaling**: daily percentage changes smoothed with **7-day SMA**, then distance from SMA scaled to 0-100 range using **min-max normalization with predefined bounds** (Investopedia) .

This approach **automatically adjusts for different volatility regimes**—same percentage deviation receives same sentiment score regardless of absolute price level. The **7-day smoothing period** balances responsiveness with noise reduction. **Unsupervised machine learning for dynamic weighting** adapts component importance based on historical predictive performance (SIS International Market Research) .

### 3.3 Multi-Asset Sentiment Frameworks

**3.3.1 Cross-Asset Correlation Metrics** **Cross-asset correlations** provide information about market-wide risk appetite. **Rising correlations during stress** indicate fear-driven indiscriminate selling; **declining correlations during calm** indicate more discriminating risk assessment. Measurement involves **rolling correlations between major asset class returns** and **principal components analysis** extracting common "risk-on/risk-off" factors (CapTrader) .

Challenges include **bounded nature of correlations (-1 to 1) and non-stationary statistical properties**. Approaches use **correlation changes rather than levels**, or focus on **specific correlation pairs with stable interpretations** (Source) .

**3.3.2 Global Risk Appetite Indicators** **Global risk appetite indices** synthesize sentiment across multiple asset classes and geographies. Common approaches include **principal component extraction from diverse asset returns**, with first component typically representing global risk appetite. Characteristics to evaluate: **component transparency, historical backtest reliability, update timeliness** (Source) .

Integration into domestic indices requires attention to **global-local sentiment relationships**. In highly integrated markets, global risk appetite may dominate local factors; in segmented markets, local sentiment may have independent predictive power. **Empirical analysis of these relationships guides appropriate weighting** (Public.com) .

**3.3.3 Sector-Rotation Sentiment Signals** **Sector rotation patterns** provide granular sentiment information. **Cyclical sector outperformance** (technology, industrials, materials) indicates growth optimism and risk appetite; **defensive sector outperformance** (utilities, consumer staples, healthcare) indicates pessimism and risk aversion. **Interest-rate-sensitive sector relative performance** indicates monetary policy expectations (Source) .

Measurement involves **relative strength of sector indices**, **flow data into sector funds**, and **options market positioning by sector**. Aggregation to overall market sentiment or use for **tactical allocation decisions** depends on specific application objectives (Source) .

## 4. Mathematical Methodology

### 4.1 Data Normalization Techniques

**4.1.1 Min-Max Scaling to 0-100 Range** **Min-max scaling** transforms values to specified range using linear interpolation: **Scaled Value = (Raw Value - Min) / (Max - Min) × 100**. Advantages: **intuitive interpretation, guaranteed bounds**. Disadvantages: **sensitivity to outlier extremes in historical data** (greedfearindex.com) .

Implementation uses **predefined minimum and maximum thresholds**, with values outside range **clipped to 0 or 100**. This prevents extreme outliers from distorting scale and ensures index remains within interpretable bounds. **Direction inversion** required for indicators where higher raw values indicate fear (e.g., VIX): **Scaled Value = 100 - (Raw Value - Min) / (Max - Min) × 100** (cloudsway.ai) .

**4.1.2 Z-Score Standardization** **Z-score standardization** converts to standard deviation units: **Z = (Value - Mean) / Standard Deviation**. Preserves **distributional shape, enables probabilistic interpretation** (values beyond ±2 occur ~5% of time under normality). However, **financial market fat tails and skewness** make normal distribution assumptions approximate (Alternative.me) .

For bounded sentiment scales, z-scores require **subsequent transformation**: **cumulative distribution function mapping** or **sigmoid functions** to 0-100 range while preserving relative ordering. **Robust alternatives** include **median absolute deviation (MAD) scaling** for outlier resistance (RavenPack) .

**4.1.3 Percentile Ranking Methods** **Percentile ranking** expresses current value relative to historical distribution: **"90th percentile" indicates conditions exceeded only 10% historically**. **Distribution-free**, making no assumptions about underlying shape. **Non-parametric robustness** valuable for financial data with unknown distributions (ACFR - AUT) .

**Rolling percentile calculation** using recent history (1-3 years) adapts to evolving conditions while maintaining comparability. **Expanding windows** incorporate all history for stability but may become dated. **Window length selection** balances adaptation speed with estimation stability (Source) .

### 4.2 Component Aggregation Approaches

**4.2.1 Equal Weighting Schemes** **Equal weighting** assigns identical importance to all components, implementing principle that **diverse sentiment dimensions deserve balanced representation**. Simple, transparent, robust to correlation—**highly correlated components automatically receive appropriate collective weight**. Avoids subjective importance judgments and **reduces overfitting risk** from optimized weights (heygotrade.com) .

Formula: **Final Index = Average(Component Scores)**. For seven components, each contributes **~14.3%**. Historical analysis demonstrates effectiveness in capturing broad sentiment trends. **Primary criticism**: potential dilution of high-quality indicators by noisy ones; failure to exploit variation in component predictive power (QuantConnect) .

**4.2.2 Subjective Weighting by Importance** **Subjective weighting** allows expert judgment to influence component importance based on **theoretical reasoning or empirical observation**. Common justifications: **volatility's direct fear measurement justifying higher weight**; **momentum's trend-following tendency suggesting lower weight for contrarian applications** (supertype.ai) .

Crypto index weights (volatility and momentum/volume at **25%** each, social media at **15%**, dominance and trends at **10%** each) reflect **subjective judgments about crypto market sentiment drivers**. Risks: **confirmation bias in weight selection, overreaction to recent performance, difficulty justifying weights to stakeholders**. Requires **ongoing review and transparent documentation of rationale** (Equiti) .

**4.2.3 Time-Varying Dynamic Weights** **Dynamic weighting** allows component importance to evolve with market conditions, recognizing that **indicator predictive power varies across regimes**. **Recession forecasting indicators may dominate during downturns; momentum indicators during trend periods** (Axiory Global) .

Implementation approaches: **regime-switching models with state-dependent weights**; **rolling optimization based on recent predictive performance**. Indonesian implementation employed **PCA, ICA, and factor analysis with final weights as mean across methods** (Source) .

**Primary risk: overfitting to historical patterns that may not persist**. Robust implementations employ **conservative adaptation speeds and out-of-sample validation** to ensure dynamic weights genuinely improve performance (greedfearindex.com) .

### 4.3 Advanced Statistical Methods

**4.3.1 Principal Component Analysis (PCA)** **PCA identifies orthogonal linear combinations maximizing explained variance**. First principal component often captures **common sentiment factor**; loadings indicate each indicator's contribution. Indonesian PCA highlighted **market momentum and exchange rate as dominant variance-explaining components** (Investopedia) .

**PCA-based weighting** uses component loadings to determine indicator weights, with **higher absolute loadings indicating greater contribution to principal sentiment dimension**. This **data-driven approach complements subjective judgment** with empirical pattern identification. However, **variance-maximization may overweight volatile components regardless of genuine sentiment relevance** (Source) .

**4.3.2 Independent Component Analysis (ICA)** **ICA separates mixed signals into statistically independent sources**, potentially identifying **distinct sentiment drivers that PCA's correlation-focused approach might miss**. Indonesian ICA emphasized **volume breadth and exchange rate as independent drivers** (greedfearindex.com) .

ICA's **independence focus** proves valuable when sentiment has **multiple underlying causes with different manifestations across components**. However, **assumption of independent sources may be violated** in financial markets where components are genuinely correlated through common causal factors (Source) .

**4.3.3 Factor Analysis for Dimensionality Reduction** **Factor analysis models observed components as manifestations of fewer unobserved latent factors**, providing **interpretable sentiment dimensionality reduction**. Indonesian factor analysis identified **two latent factors**: one aligned with **market momentum, price strength, and volume breadth** (common sentiment factor); another capturing **volatility and interest rate** (risk dimension) (Source) .

Factor analysis's **explicit modeling of measurement error** distinguishes it from PCA, potentially providing **more robust latent factor identification** when components contain significant noise. Factor structure also **facilitates interpretation by grouping related indicators** (finhacker.cz) .

### 4.4 Smoothing and Trend Detection

**4.4.1 Simple Moving Average Applications** **Simple moving averages (SMA)** smooth time series by averaging over specified windows. **Longer windows provide greater smoothing**. Indonesian implementation employed **7-day SMA** for component calculation, balancing trend capture with recent sensitivity (Personal Finance & Money Stack Exchange) .

SMA formula: **SMA_t = (Value_t + Value_{t-1} + ... + Value_{t-n+1}) / n**. **Uniform weighting** creates equal influence for all observations in window, which may **lag genuine turning points**. **Adaptive window lengths** or **multiple horizon combinations** address this limitation (Source) .

**4.4.2 Exponential Weighting Techniques** **Exponential moving averages (EMA)** apply **decreasing weights to older observations**, providing **greater responsiveness to recent changes** while maintaining smoothing. Formula: **EMA_t = × Value_t + (1- ) × EMA_{t-1}**, where **= 2/(n+1)** for n-period equivalent (yahoo.com) .

EMAs are **central to McClellan Oscillator construction** (19-day and 39-day EMAs of net advances). The **smoothing parameter can be adapted** to market conditions—**higher (shorter effective window) during high volatility; lower during calm periods** (Source) .

**4.4.3 Distance-from-Trend Calculations** **Distance-from-trend measures** quantify how far current values deviate from smoothed trend, identifying **potential extremes and reversal points**. Indonesian implementation calculated **distance from SMA based on percentage changes**, then scaled to 0-100 range (Source) .

This approach **automatically normalizes for different volatility regimes**—same percentage deviation receives same sentiment score regardless of absolute level. **Multiple trend horizons** (short, intermediate, long-term) can be combined for **comprehensive sentiment assessment across timeframes** (Biblioteka Nauki) .

## 5. Interpretation and Application

### 5.1 Sentiment Classification Framework

| Zone | Score Range | Characteristics | Typical Market Conditions |
|---|---|---|---|
| **Extreme Fear** | 0-24 | Panic selling, capitulation, maximum pessimism | Market bottoms, forced liquidations, crisis periods |
| **Fear** | 25-49 | Defensive positioning, risk aversion, uncertainty | Corrections, early recovery, consolidation |
| **Neutral** | 50 | Balanced sentiment, no clear directional bias | Trendless markets, transition periods |
| **Greed** | 51-75 | Optimism, risk-taking, momentum chasing | Established uptrends, broad participation |
| **Extreme Greed** | 76-100 | Euphoria, speculation, complacency about risk | Market tops, bubble conditions, narrow leadership |

*Table 3: Sentiment Zone Classification Framework*

**5.1.1 Extreme Fear Thresholds (0-24)** **Extreme fear** indicates **panic-driven market conditions where selling pressure has become climactic**. Quantitative signatures include: **VIX above 40**, **put/call ratios exceeding 1.5**, **credit spreads widening to 1000+ basis points**, **advance-decline ratios below 0.1**, and **safe haven assets outperforming equities by 10%+ over 20 days** (Source) .

**Contrarian interpretation**: Extreme fear zones have **historically marked optimal long-term entry points**, with subsequent 12-month returns significantly exceeding average market performance. However, **timing precision is low**—fear can persist for weeks or months, and **fundamental deterioration may justify continued pessimism**. **Position sizing should reflect uncertainty**, with gradual accumulation rather than all-in deployment (Source) .

**5.1.2 Fear Zone Characteristics (25-49)** **Fear zone** indicates **elevated risk aversion without full panic**. Investors are **defensively positioned but not capitulating**. Market conditions typically show: **negative momentum but not extreme**, **elevated volatility but not crisis levels**, **credit spreads wider than normal but not distressed**, and **mixed safe haven flows** (cbs.dk) .

**Tactical implications**: Fear zone may represent **early recovery opportunity or continued consolidation**. **Confirmation from technical indicators** (divergences, volume patterns) improves timing. **Partial position building** with room to add on further weakness is often appropriate (Alternative.me) .

**5.1.3 Neutral Range Dynamics (50)** **Neutral sentiment (score near 50)** indicates **balanced market psychology with no clear directional bias**. This condition is **relatively rare and typically short-lived**, as market emotion tends toward extremes. Neutral readings often occur **during transition periods between greed and fear cycles** (Source) .

**Strategic implications**: Neutral conditions favor **trend-following rather than contrarian approaches**, as directional bias is unclear. **Momentum strategies** may perform well; **mean-reversion strategies** should be tempered. Neutral periods can persist for **extended consolidation phases** where neither bulls nor bears achieve dominance (Wall Street Oasis) .

**5.1.4 Greed Zone Indicators (51-75)** **Greed zone** indicates **optimistic sentiment with active risk-taking**. Market conditions show: **positive momentum with broad participation**, **compressed volatility expectations**, **narrow credit spreads**, **heavy call option buying**, and **risk asset outperformance of safe havens** (supertype.ai) .

**Risk management focus**: Greed zone is **not immediate sell signal**—healthy bull markets can persist with sustained greed readings. However, **position sizing should reflect elevated valuations**, and **stop-loss discipline becomes critical**. **Divergences between sentiment and price action** (e.g., index rising with narrowing breadth) warrant heightened attention (Source) .

**5.1.5 Extreme Greed Signals (76-100)** **Extreme greed** indicates **euphoric conditions where risk is systematically underpriced**. Quantitative signatures: **VIX below 12**, **put/call ratios below 0.6**, **credit spreads below 300 basis points**, **record highs in momentum and breadth**, and **speculative assets outperforming fundamentals** (supertype.ai) .

**Contrarian interpretation**: Extreme greed zones have **historically preceded significant corrections or bear markets**, though timing is highly uncertain. **Defensive positioning, profit-taking,**

**and hedging** are appropriate. **Narrowing market breadth during extreme greed** (fewer stocks participating in advance) is particularly reliable warning sign (Quantified Strategies) .

### 5.2 Tactical Investment Applications

**5.2.1 Contrarian Position Sizing** **Position sizing based on sentiment extremes** balances opportunity against risk of premature entry/exit. Common approaches:

| Sentiment Zone | Equity Allocation vs. Baseline | Implementation Notes |
|---|---|---|
| Extreme Fear (0-24) | +20-40% overweight | Gradual accumulation, multi-entry strategy |
| Fear (25-49) | +10-20% overweight | Partial positions, room to add |
| Neutral (50) | Baseline allocation | Trend-following, momentum emphasis |
| Greed (51-75) | -10-20% underweight | Reduced exposure, tighter stops |
| Extreme Greed (76-100) | -20-40% underweight | Defensive positioning, active hedging |

*Table 4: Sentiment-Based Position Sizing Framework*

**Key principle**: Sentiment extremes provide **probabilistic edge, not certainty**. Sizing should reflect **confidence in signal, investment horizon, and risk tolerance** (Source) .

**5.2.2 Entry and Exit Timing** **Timing refinement beyond zone identification** employs:

- **Technical confirmation**: Divergences, volume patterns, support/resistance breaks
- **Momentum of sentiment itself**: Rising fear from extreme levels = early recovery; falling greed from extreme levels = early correction
- **Fundamental validation**: Ensure sentiment extreme not justified by genuine deterioration/improvement
- **Multi-timeframe alignment**: Daily, weekly, monthly sentiment in same zone increases confidence (allwinacademy.com)

**Common timing errors**: Entering too early in fear zone (before capitulation complete); exiting too early in greed zone (before momentum exhausts); ignoring fundamental changes that justify sentiment shift (Source) .

**5.2.3 Risk Management Integration** **Risk management for sentiment-based strategies**:

- **Stop-loss rules**: Maximum loss per position, maximum portfolio drawdown triggers
- **Position concentration limits**: No single position exceeds threshold; sector/industry caps
- **Correlation monitoring**: Ensure "diversified" positions not highly correlated in stress
- **Liquidity reserves**: Maintain cash/bonds for opportunistic deployment
- **Rebalancing frequency**: Regular rebalancing to target allocations, not just sentiment triggers (Source)

### 5.3 Strategic Asset Allocation

**5.3.1 Long-Term Regime Identification** **Sentiment indices identify major market regimes** with different risk-return characteristics:

| Regime | Sentiment Pattern | Typical Duration | Strategic Posture |
|---|---|---|---|
| Secular bull | Sustained greed with periodic fear corrections | 5-10+ years | Core equity overweight, buy dips |
| Secular bear | Sustained fear with periodic greed rallies | 5-15+ years | Defensive core, tactical trading |
| Cyclical transition | Rapid sentiment oscillation | 1-3 years | Flexible, adaptive approach |
| Crisis | Extreme fear persistence | Weeks to months | Maximum opportunism, liquidity focus |

*Table 5: Market Regime Identification Framework*

**Regime identification** combines **sentiment trend, fundamental valuation, and macroeconomic context** rather than relying on sentiment alone (CapTrader) .

**5.3.2 Dynamic Rebalancing Triggers** **Sentiment-based rebalancing** adjusts portfolio weights when sentiment reaches configured thresholds:

- **Rebalancing bands**: Adjust when sentiment-driven allocation deviates ±5% from target
- **Threshold triggers**: Rebalance when sentiment enters/exits extreme zones
- **Time-based minimum**: No rebalancing more frequent than monthly (reduce transaction costs)
- **Tax and cost consideration**: Incorporate transaction costs, tax implications in rebalancing decisions (quanttekel.com)

**5.3.3 Multi-Asset Portfolio Construction** **Multi-asset sentiment integration** extends beyond equities to:

- **Fixed income**: Credit spread sentiment for corporate bond allocation; yield curve sentiment for duration positioning
- **Alternatives**: Commodity sentiment for real asset exposure; real estate sentiment for REIT allocation
- **Geographic**: Regional sentiment indices for international allocation
- **Currency**: Safe haven sentiment for currency hedging decisions (stockgeist.ai)

### 5.4 Limitations and Caveats

**5.4.1 Lagging vs. Leading Indicator Debate** **Sentiment indices have both leading and lagging properties**:

- **Leading aspects**: Options market positioning often precedes price moves; credit spreads typically lead equity turns
- **Lagging aspects**: Momentum and breadth measures confirm trends already underway; extreme readings often require catalyst for reversal

**Resolution**: Sentiment indices are **most valuable as contextual tools confirming or questioning price action**, not as standalone timing mechanisms. **Combination with fundamental and technical analysis** improves predictive power (TradeFundrr) .

**5.4.2 Market Structure Evolution Effects** **Structural changes affecting sentiment index reliability**:

| Change | Impact on Sentiment Measurement | Mitigation Approach |
|---|---|---|
| Rise of passive investing | Reduced price discovery, momentum persistence | Adjust momentum lookback periods, weight breadth more heavily |
| Algorithmic trading | Faster sentiment shifts, flash crashes | Higher frequency data, shorter smoothing windows |
| Central bank intervention | Suppressed volatility, distorted credit spreads | Incorporate policy regime indicators, adjust normalization baselines |
| Retail trading surge (2020+) | Social media amplification, meme stock dynamics | Enhanced social sentiment integration, volatility regime detection |

*Table 6: Market Structure Evolution and Adaptation*

**Ongoing calibration** required to maintain index relevance as market structure evolves (Young Platform Academy) .

**5.4.3 Overfitting and Data Mining Risks** **Backtest overfitting**—optimizing parameters to historical data that don't generalize—is **pervasive risk in sentiment index construction**. Warning signs: **too many parameters relative to observations**, **excellent in-sample performance with poor out-of-sample results**, **lack of theoretical justification for optimized values** (Investopedia) .

**Mitigation strategies**:

- **Theoretical grounding**: Prefer theoretically justified parameters over optimized ones
- **Out-of-sample testing**: Validate on data not used in construction
- **Cross-market validation**: Test whether parameters transfer to related markets
- **Simplicity preference**: Favor simpler models with fewer parameters
- **Economic significance**: Focus on economically meaningful effects, not just statistical significance (Source)

## 6. Data Infrastructure and Technology Stack

### 6.1 Data Source Categories

**6.1.1 Exchange Feeds and Market Data APIs** **Primary market data sources** for sentiment index construction:

| Data Category | Typical Sources | Cost Structure | Update Frequency |
|---|---|---|---|
| Equity prices | Bloomberg, Refinitiv, Exchange APIs (IEX, Polygon) | $500-5000+/month | Real-time, delayed, or end-of-day |
| Options data | CBOE LiveVol, ORATS, CME Group | $1000-10000+/month | Intraday snapshots or real-time |

Table 7 – continued

| Data Category | Typical Sources | Cost Structure | Update Frequency |
|---|---|---|---|
| Fixed income | ICE Data Services, Bloomberg, TRACE | $1000-5000+/month | End-of-day, some intraday |
| FX data | Refinitiv, 360T, central bank feeds | $500-3000+/month | Real-time |

*Table 7: Primary Market Data Source Comparison*

**Selection criteria**: **Coverage breadth, historical depth, data quality, API reliability, cost-effectiveness** for specific use case (Biblioteka Nauki) .

**6.1.2 Alternative Data Providers** **Emerging data sources** for sentiment enhancement:

- **Social media**: Twitter/X API (academic/commercial tiers), Reddit API, specialized sentiment providers (SentimentTrader, StockTwits)
- **Search trends**: Google Trends API, Bing Search Insights
- **Satellite/IoT**: Orbital Insight (retail parking, construction), RS Metrics (metal storage)
- **Consumer behavior**: Credit card aggregators, foot traffic data
- **Web scraping**: Earnings call transcripts, SEC filings, news sentiment (ScienceDirect)

**Evaluation framework**: **Signal novelty, correlation with existing indicators, decay speed, cost, compliance requirements** (ScienceDirect) .

**6.1.3 Web Scraping and Unstructured Data** **Custom data collection** for specialized needs:

- **Regulatory filings**: EDGAR, company investor relations pages
- **News and commentary**: RSS feeds, news APIs, specialized financial media
- **Earnings calls**: Transcript services, audio analysis
- **Academic research**: SSRN, NBER working papers for leading indicators

**Technical considerations**: **Rate limiting, terms of service compliance, data quality validation, storage and processing infrastructure** (semanticscholar.org) .

### 6.2 Programming Environment

**6.2.1 Python Ecosystem (pandas, numpy, scikit-learn)** **Python dominates quantitative finance** due to rich ecosystem:

| Library | Purpose | Key Functions for Sentiment Indices |
|---|---|---|
| **pandas** | Data manipulation | Time-series alignment, rolling calculations, resampling |
| **numpy** | Numerical computing | Array operations, mathematical functions, linear algebra |
| **scikit-learn** | Machine learning | PCA, factor analysis, preprocessing, model selection |
| **statsmodels** | Statistical modeling | Time-series analysis, regression, hypothesis testing |
| **TA-Lib** | Technical analysis | 150+ technical indicators including momentum, volatility |

Table 8 – continued

| Library | Purpose | Key Functions for Sentiment Indices |
|---|---|---|
| **yfinance, pandas-datareader** | Data retrieval | Free historical data from Yahoo Finance, FRED, etc. |

*Table 8: Core Python Libraries for Sentiment Index Development*

**Production considerations**: **Environment management (conda, poetry), testing (pytest), documentation (Sphinx, Jupyter), deployment (Docker, cloud functions)** (Axiory Global) .

**6.2.2 R Statistical Computing** **R offers advantages** for statistical rigor and reproducibility:

- **Superior statistical packages**: tidyverse for data manipulation, quantmod for quantitative analysis, rugarch for volatility modeling
- **Academic research integration**: Direct implementation of published methodologies
- **Visualization**: ggplot2 for publication-quality graphics, shiny for interactive dashboards

**Typical use**: **Research and prototyping**, with production implementation in Python or compiled languages for performance (Wall Street Oasis) .

**6.2.3 Cloud-Based Analytics Platforms** **Cloud deployment options**:

| Platform | Strengths | Best For |
|---|---|---|
| **AWS (SageMaker, Lambda, RDS)** | Comprehensive services, enterprise integration | Large-scale production, complex pipelines |
| **Google Cloud (BigQuery, AI Platform)** | Big data analytics, ML capabilities | High-volume data, advanced analytics |
| **Microsoft Azure** | Enterprise integration, hybrid cloud | Microsoft-centric organizations |
| **Databricks** | Unified analytics, collaborative notebooks | Team-based development, ML workflows |
| **QuantConnect, Alpaca** | Finance-specific, integrated trading | Rapid strategy deployment, algorithmic trading |

*Table 9: Cloud Platform Comparison for Sentiment Index Deployment*

### 6.3 Visualization and Delivery

**6.3.1 Real-Time Dashboard Design** **Effective sentiment dashboard elements**:

- **Primary gauge**: Large, prominent 0-100 sentiment score with color-coded zone
- **Historical chart**: 1-5 year history with zone shading, major events annotated
- **Component breakdown**: Stacked area or radar chart showing individual contributions
- **Market context**: Price index overlay, key statistics (VIX, put/call ratio, spreads)
- **Alert status**: Current zone, distance to next threshold, recent changes (Public.com)

**Design principles**: **Clarity over complexity, mobile responsiveness, accessibility (color blindness), performance (sub-second load)** (Personal Finance & Money Stack Exchange) .

#### 6.3.2 Historical Backtesting Interfaces

**Backtesting visualization capabilities**:

- **Signal history**: When did index enter/exit each zone?
- **Performance attribution**: Returns following each signal type
- **Regime analysis**: How did index perform in different market conditions?
- **Parameter sensitivity**: How do results change with different thresholds, weights, lookback periods?
- **Comparison tools**: Side-by-side with buy-and-hold, other strategies (yahoo.com)

#### 6.3.3 Alert and Notification Systems

**Alert configuration options**:

| Alert Type | Trigger Condition | Delivery Method | Use Case |
|---|---|---|---|
| Zone entry/exit | Index crosses zone threshold | Email, SMS, webhook, in-app | Tactical rebalancing |
| Extreme reading | Index enters extreme fear/greed | Multiple channels, escalation | Major opportunity/risk |
| Component divergence | Individual component extreme vs. composite | Dashboard highlight, daily digest | Early warning, deeper analysis |
| Trend change | 5-day MA crosses 20-day MA | Email, dashboard | Momentum confirmation |
| Custom threshold | User-defined level | User-selected | Personalized strategy |

*Table 10: Alert System Configuration Framework*

---

# Document B: Step-by-Step Implementation Roadmap

## Phase 1: Project Definition and Scoping

### 1.1 Establish Project Parameters

#### 1.1.1 Define Target Market and Asset Class

**Decision framework for market selection**:

| Factor | Considerations | Impact on Implementation |
|---|---|---|
| **Data availability** | Exchange APIs, historical depth, real-time access | Determines component feasibility |
| **Market liquidity** | Trading volume, options market development | Affects indicator quality, especially options-based components |
| **User relevance** | Investment universe, geographic focus | Drives prioritization of specific markets |
| **Competitive landscape** | Existing sentiment products, differentiation opportunity | Informs positioning and feature prioritization |

**Recommended starting point**: **Broad U.S. equity market (S&P 500)** due to data richness, liquid options, and extensive historical record. Expand to **cryptocurrency** or **emerging markets** for specialized applications (Source) .

### 1.1.2 Determine Update Frequency (Real-Time, Daily, Weekly)

| Frequency | Data Requirements | Computational Load | Use Case Alignment | Typical Implementation |
|---|---|---|---|---|
| **Real-time** | Streaming market data, sub-second latency | High, requires stream processing infrastructure | High-frequency trading, algorithmic execution | WebSocket feeds, in-memory computation, microsecond response |
| **Intraday** | 15-60 minute snapshots | Moderate, batch processing with scheduled updates | Day trading, intraday risk management | Scheduled API pulls, cached calculations, minute-level updates |
| **Daily** | End-of-day prices, daily options settlement | Low, overnight batch processing sufficient | Swing trading, tactical asset allocation, research | Nightly cron jobs, historical database, morning publication |
| **Weekly** | Weekly closes, aggregated flows | Minimal, manual calculation feasible | Long-term strategic allocation, academic research | Weekly manual or automated update, newsletter format |

*Table 11: Update Frequency Decision Framework*

**Recommendation**: **Daily updates** for most applications—balances timeliness with implementation complexity. **Intraday** for active trading operations; **real-time** only with specific high-frequency requirements (greedfearindex.com) .

### 1.1.3 Identify End Users and Use Cases

| User Type | Primary Use Case | Key Requirements | Feature Priorities |
|---|---|---|---|
| **Individual investors** | Personal portfolio timing, education | Simple interpretation, clear signals, low cost | Intuitive dashboard, mobile access, educational content |
| **Financial advisors** | Client communication, risk management | Professional credibility, customizable alerts, reporting | White-label options, client-facing materials, CRM integration |
| **Institutional traders** | Algorithmic signals, risk management | API access, low latency, backtested performance | Direct market data feeds, execution integration, audit trails |
| **Asset managers** | Strategic allocation, product development | Academic rigor, regulatory compliance, scalability | Institutional data sources, compliance documentation, multi-asset capability |
| **Researchers/ academics** | Market efficiency studies, model validation | Historical depth, methodological transparency, reproducibility | Full data access, open-source code, publication-ready outputs |

*Table 12: End User Requirements Analysis*

**1.1.4 Set Historical Backtest Requirements** **Minimum viable backtest**: **10 years of daily data** covering at least one complete market cycle (bull and bear). **Preferred**: **20+ years** including multiple cycles, crisis periods (2000, 2008, 2020), and varying monetary policy regimes (FinMasters) .

**Backtest quality checklist**:

- **Data survivorship bias addressed**: Include delisted securities, historical index constituents
- **Look-ahead bias eliminated**: Use only information available at each point in time
- **Transaction costs incorporated**: Slippage, commissions, market impact for realistic returns
- **Out-of-sample validation**: Reserve recent period or separate market for true testing
- **Statistical significance**: Sufficient observations for reliable inference
- **Economic significance**: Meaningful return differences after costs, not just statistical significance

### 1.2 Component Selection Matrix

#### 1.2.1 Evaluate Data Availability for Each Candidate Component

| Component | Minimum Data Requirements | Typical Sources | Availability Assessment |
|---|---|---|---|
| **Price momentum (125-day ROC)** | Daily closing prices, 125+ days history | Exchange APIs, Yahoo Finance, FRED | **Universal** —available for virtually all markets |
| **Moving average deviation** | Daily prices, 125+ days for SMA calculation | Same as above | **Universal** |
| **52-week highs/lows** | Daily prices for universe constituents, 252+ days history; constituent list | Exchange data, index provider feeds | **Broad equity markets** — requires constituent data; challenging for some emerging markets |
| **Stocks above MA** | Same as highs/lows | Same as above | **Same constraints** |
| **Volume-weighted breadth** | Daily prices, volumes for universe constituents | Exchange data | **Most developed markets** — volume data quality varies |
| **VIX or volatility** | Options prices for volatility index calculation; or high-frequency prices for realized vol | CBOE (VIX), exchange tick data, ORATS | **Developed equity markets with liquid options**; realized vol possible everywhere with tick data |
| **Put/call ratio** | Options volume or open interest by put/call, daily | CBOE, OCC, exchange feeds | **US and major developed markets**; limited in emerging markets |
| **Credit spreads** | Corporate bond yields/indices, Treasury yields | ICE, Bloomberg, TRACE, central bank data | **Developed credit markets**; emerging market sovereign spreads more available |
| **Safe haven differential** | Equity and government bond total return indices | Same as price data plus bond index data | **Most markets with liquid government bond market** |

*Table 13: Component Data Availability Assessment*

#### 1.2.2 Assess Computational Complexity

| Complexity Tier | Components | Implementation Effort | Runtime Characteristics |
|---|---|---|---|
| **Low** | Price momentum, moving average deviation, simple breadth counts | Hours to days; standard library functions | Milliseconds per calculation |
| **Medium** | Volume-weighted metrics, volatility calculations, put/call ratios | Days to weeks; some custom code required | Seconds per calculation |
| **High** | Options implied volatility (full surface), advanced statistical methods (PCA, dynamic weights), real-time stream processing | Weeks to months; significant custom development, infrastructure | Minutes for batch; sub-second for optimized real-time |

**Recommendation**: Start with **low and medium complexity components**, add high-complexity features based on user requirements and resource availability (Source) .

**1.2.3 Prioritize Components by Predictive Power** Based on academic literature and practitioner experience:

| Priority | Component | Predictive Evidence | Primary Signal |
|---|---|---|---|
| **1 (Core)** | Volatility (VIX or realized) | Strongest single predictor of future returns; extensive academic validation | Fear/greed intensity |
| **1 (Core)** | Credit spreads | Leading indicator of economic stress and equity returns; credit market information advantage | Risk appetite, economic health |
| **2 (Important)** | Put/call ratio | Reliable contrarian indicator, especially at extremes; options market information content | Positioning, hedging demand |
| **2 (Important)** | Market breadth (advance-decline, highs/lows) | Confirms trend health, identifies divergences; breadth deterioration precedes tops | Participation, trend sustainability |

Table 16 – continued

| Priority | Component | Predictive Evidence | Primary Signal |
|---|---|---|---|
| **3 (Valuable)** | Momentum and moving average deviation | Trend-following complement to contrarian measures; identifies extended conditions | Trend strength, mean reversion potential |
| **3 (Valuable)** | Safe haven flows | Cross-asset validation of risk appetite; flight-to-quality dynamics | Capital allocation, risk preference |
| **4 (Supplementary)** | Options skew, flow data, advanced statistical combinations | Incremental information, especially in specific regimes; higher complexity | Tail risk, informed positioning, factor structure |

*Table 14: Component Prioritization Framework*

**1.2.4 Document Rationale for Inclusion/Exclusion** **Required documentation for each component**:

- **Theoretical justification**: Why should this indicator reflect sentiment?
- **Empirical evidence**: What research supports its predictive power?
- **Data requirements**: Specific data sources, frequency, history needed
- **Calculation methodology**: Formula, parameters, edge cases
- **Normalization approach**: How raw values transform to comparable scale
- **Weighting rationale**: Why this component receives its specific weight
- **Limitations and caveats**: When might this indicator fail or mislead?

### 1.3 Technical Architecture Planning

#### 1.3.1 Cloud vs. On-Premises Infrastructure Decision

| Factor | Cloud Preferred | On-Premises Preferred |
|---|---|---|
| **Initial capital** | Low upfront, pay-as-you-scale | High upfront, depreciated over time |
| **Operational expertise** | Limited in-house DevOps, prefer managed services | Strong in-house infrastructure team |
| **Scalability needs** | Unpredictable or rapidly growing demand | Stable, predictable workload |
| **Latency requirements** | Moderate (milliseconds acceptable) | Extreme (microseconds critical) |
| **Data sensitivity** | Standard market data, no proprietary concerns | Highly proprietary strategies or data |
| **Regulatory environment** | Standard compliance requirements | Specialized regulatory constraints |
| **Geographic distribution** | Global user base, need edge locations | Concentrated local user base |

**Recommendation**: **Cloud-first for most implementations**; evaluate on-premises only for specific latency or regulatory requirements. **Hybrid approaches** (cloud for historical analysis, on-premises for execution) common in institutional settings (QuantConnect) .

### 1.3.2 Database Schema Design for Time-Series Data

**Core tables for sentiment index database**:

| Table | Purpose | Key Fields | Indexing |
|---|---|---|---|
| `market_data` | Raw price, volume, fundamental data | `date`, `ticker`, `open`, `high`, `low`, `close`, `volume`, `source` | Primary: (`date`, `ticker`); Secondary: `ticker` for time-series queries |
| `options_data` | Options prices, volume, open interest | `date`, `underlying`, `expiration`, `strike`, `put_call`, `bid`, `ask`, `volume`, `oi` | Primary: (`date`, `underlying`, `expiration`, `strike`); Secondary: `underlying`, `date` for term structure |
| `economic_data` | Macroeconomic releases, policy rates | `date`, `indicator`, `value`, `revision_flag`, `source` | Primary: (`date`, `indicator`); Secondary: `indicator` for series retrieval |
| `sentiment_components` | Calculated raw indicator values | `date`, `component_name`, `raw_value`, `normalized_value`, `parameters_used` | Primary: (`date`, `component_name`); Secondary: `component_name` for history |
| `sentiment_index` | Final composite index values | `date`, `index_value`, `zone`, `component_weights`, `version` | Primary: `date`; Secondary: `zone` for regime analysis |
| `alerts_log` | Threshold crossings, notifications sent | `timestamp`, `alert_type`, `trigger_value`, `notification_channels`, `status` | Primary: `timestamp`; Secondary: `alert_type`, `status` for management |

*Table 15: Core Database Schema for Sentiment Index System*

**Technology selection**: **TimescaleDB or InfluxDB** for high-frequency time-series; **PostgreSQL** with appropriate indexing for standard daily data; **Parquet files on cloud storage** for historical archive (Source) .

### 1.3.3 API Integration Requirements Mapping

| Integration Type | Purpose | Protocol/Format | Authentication | Error Handling |
|---|---|---|---|---|
| **Market data feed** | Real-time prices, volumes | WebSocket, FIX, proprietary | API keys, certificates | Reconnection logic, stale data detection, failover to backup |
| **Historical data bulk** | Backfill, research | REST, SFTP, cloud storage | OAuth, IAM roles | Checksum validation, partial download resume, format verification |
| **Alternative data** | Social media, search trends, satellite | REST, GraphQL, webhooks | OAuth, API keys | Rate limiting compliance, quota management, data quality checks |

Table 19 – continued

| Integration Type | Purpose | Protocol/Format | Authentication | Error Handling |
|---|---|---|---|---|
| **Notification delivery** | Alerts to users | Email (SMTP), SMS (Twilio), push (FCM/APNs), webhooks | Service credentials | Retry with exponential backoff, dead letter queue, delivery confirmation |
| **Downstream systems** | Trading execution, portfolio management | REST, gRPC, message queues (Kafka, RabbitMQ) | Mutual TLS, API keys | Idempotency, exactly-once delivery, schema versioning |

*Table 16: API Integration Requirements Matrix*

---

## Phase 2: Data Pipeline Development

### 2.1 Source Identification and Procurement

**2.1.1 Primary Market Data Vendor Evaluation** **Evaluation criteria scoring (1-5 scale)**:

| Vendor | Coverage | Quality | API Reliability | Cost | Support | Overall |
|---|---|---|---|---|---|---|
| **Bloomberg** | 5 | 5 | 4 | 2 | 5 | 4.2 |
| **Refinitiv (LSEG)** | 5 | 5 | 4 | 3 | 4 | 4.2 |
| **FactSet** | 4 | 5 | 4 | 3 | 4 | 4.0 |
| **ICE Data Services** | 4 | 4 | 4 | 4 | 4 | 4.0 |
| **IEX Cloud** | 3 | 4 | 5 | 5 | 3 | 4.0 |
| **Polygon.io** | 3 | 4 | 5 | 5 | 3 | 4.0 |
| **Alpaca** | 3 | 4 | 4 | 5 | 3 | 3.8 |
| **Yahoo Finance (free)** | 2 | 3 | 2 | 5 | 1 | 2.6 |

*Table 17: Market Data Vendor Evaluation Matrix*

**Decision framework**: **Tier 1 (Bloomberg, Refinitiv)** for institutional production; **Tier 2 (IEX, Polygon)** for cost-conscious professional implementations; **free sources** for prototyping, education, non-commercial research (sentic.net) .

**2.1.2 Backup and Redundancy Planning** **Redundancy levels**:

| Level | Configuration | RTO (Recovery Time Objective) | RPO (Recovery Point Objective) | Cost Impact |
|---|---|---|---|---|
| **Basic** | Single primary source, manual failover to free alternative | 24-48 hours | 1 day | Minimal |
| **Standard** | Dual primary sources (paid), automatic failover | 1-4 hours | 15 minutes | 2x data costs |
| **High** | Triple sources, real-time reconciliation, geographic distribution | <15 minutes | Near-zero | 3x+ data costs, infrastructure complexity |
| **Institutional** | Exchange-direct feeds, co-location, dedicated circuits | <1 minute | Zero | 10x+ costs, specialized infrastructure |

**Recommendation**: **Standard level for most production implementations**; **High** for active trading operations; **Institutional** only for specific latency-critical applications (LinkedIn) .

#### 2.1.3 Cost-Benefit Analysis of Free vs. Paid Sources

| Use Case | Free Sources Viable? | Limitations | When to Upgrade |
|---|---|---|---|
| **Personal education, prototyping** | Yes | Delayed data, rate limits, no warranty | N/A —stay with free |
| **Small advisor practice, newsletter** | Yes, with care | Reliability concerns, limited history, support | When revenue justifies, or reliability issues emerge |
| **Professional trading, institutional** | No | Insufficient reliability, compliance requirements, liability | From inception —build on solid foundation |
| **Academic research** | Often yes | Need to verify data quality, document limitations | For publication in top journals, or when grants allow |

### 2.2 Data Ingestion Implementation

#### 2.2.1 API Connection Development (REST, WebSocket, FIX)

**Connection type selection by use case**:

| Protocol | Best For | Implementation Complexity | Python Libraries |
|---|---|---|---|
| **REST** | Historical data, scheduled updates, simple requests | Low | `requests`, `httpx`, `aiohttp` |
| **WebSocket** | Real-time streaming, low-latency updates | Medium | `websockets`, `socket.io`, `aiohttp` |
| **FIX** | Institutional trading, standardized messaging | High | `quickfix`, `fix8`, custom implementations |
| **SSE (Server-Sent Events)** | One-way streaming, simpler than WebSocket | Low-Medium | `sseclient`, `requests` with stream handling |
| **gRPC** | High-performance internal services | Medium | `grpcio` |

**Code structure pattern for robust API clients**:

```python
# Abstract base class for data sources
class DataSource(ABC):
    @abstractmethod
    def connect(self): ...
    @abstractmethod
    def fetch_historical(self, symbol, start, end): ...
    @abstractmethod
    def subscribe_realtime(self, symbols, callback): ...
    @abstractmethod
    def health_check(self): ...

# Concrete implementation with retry, caching, failover
class PrimaryDataSource(DataSource):
    def __init__(self, config, backup_source=None):
        self.config = config
        self.backup = backup_source
        self.cache = LRUCache(maxsize=10000)
        self.circuit_breaker = CircuitBreaker(failure_threshold=5, recovery_timeout=60)

    @retry(stop=stop_after_attempt(3), wait=wait_exponential(multiplier=1, min=4, max=10))
    def fetch_historical(self, symbol, start, end):
        # Implementation with caching, error handling, fallback
        ...
```

(ResearchGate)

**2.2.2 Historical Data Backfill Procedures** **Backfill priority order**:

1. **Core index components**: Prices, volumes for primary benchmark (e.g., S&P 500) — minimum 10 years
2. **Component universe**: Full constituent history with corporate action adjustments — minimum 10 years
3. **Options data**: VIX history, put/call ratios — minimum 10 years, ideally 20+
4. **Credit spreads**: High-yield, investment grade indices — minimum 10 years
5. **Alternative data**: Social media, search trends — as available, typically shorter history

**Quality validation checks**:

- **Price continuity**: No unexplained gaps, suspicious zeros, or negative values
- **Volume reasonableness**: Within historical range, no anomalous spikes without explanation
- **Return distribution**: Statistical properties consistent with known market behavior
- **Cross-source validation**: Compare overlapping periods from multiple sources
- **Corporate action accuracy**: Splits, dividends, spin-offs correctly applied (ScienceDirect)

**2.2.3 Real-Time Stream Processing Setup** **Architecture pattern for real-time sentiment calculation**:

```
┌──────────────────┐     ┌──────────────────┐     ┌──────────────────┐
│  Market Data     │────│  Stream          │────│  Component       │
│  Feeds (Kafka,   │     │  Processing      │     │  Calculators     │
│  Pulsar, Kinesis)│     │  (Flink, Spark   │     │  (stateful,      │
│                  │     │  Streaming,      │     │  windowed)       │
│                  │     │  custom)         │     │                  │
└──────────────────┘     └──────────────────┘     └──────────────────┘
                                                          │
                                  ┌──────────────────────┘
                                  ▼
                        ┌──────────────────┐
                        │  Index           │
                        │  Aggregator      │
                        │  (weighted       │
                        │  average,        │
                        │  smoothing)      │
                        └──────────────────┘
                                  │
                  ┌───────────────┼────────────────┐
                  ▼               ▼                ▼
            ┌────────────┐    ┌────────────┐    ┌────────────┐
            │  Database  │    │  Cache     │    │  Alert     │
            │  (persist)│    │  (fast     │    │  Engine    │
            │            │    │  query)    │    │            │
            └────────────┘    └────────────┘    └────────────┘
```

**Technology stack options**:

| Layer | Open Source | Managed Cloud | Commercial |
|---|---|---|---|
| Messaging | Kafka, Pulsar, NATS | AWS Kinesis, Google Pub/Sub, Azure Event Hubs | Confluent, Aiven |
| Stream Processing | Flink, Spark Streaming, Kafka Streams | AWS Kinesis Analytics, Google Dataflow, Azure Stream Analytics | Ververica, Databricks |
| State Store | Redis, RocksDB | AWS ElastiCache, Google Memorystore | — |
| Time-Series DB | TimescaleDB, InfluxDB, QuestDB | AWS Timestream, Google BigQuery (time-series), Azure Time Series Insights | Timescale Cloud, InfluxDB Cloud |

(ScienceDirect)

### 2.3 Data Quality Assurance

#### 2.3.1 Missing Data Handling Protocols

| Scenario | Detection Method | Handling Strategy | Documentation |
|---|---|---|---|
| **Single point gap** | Null check, timestamp continuity | Linear interpolation if <3 sessions; flag if larger | Log interpolation, retain original null |
| **Extended outage** | Gap >5 sessions, multiple sources affected | Use backup source; if unavailable, halt index publication with explanation | Incident log, user notification |
| **Delayed data** | Timestamp vs. receipt time lag | Tolerance threshold (e.g., 15 min); beyond threshold, use stale data with flag | Latency monitoring dashboard |
| **Partial universe** | Constituent count check | If >10% missing, use available subset with adjusted normalization; if >30%, halt | Coverage statistics, methodology note |
| **Intraday interruption** | Heartbeat monitoring | Switch to last valid calculation; resume when feed restored | Status page update, alert to ops |

(王亚南经济研究院)

#### 2.3.2 Outlier Detection and Correction

**Statistical outlier detection methods**:

| Method | Best For | Implementation | Threshold Example |
|---|---|---|---|
| **Z-score** | Approximately normal distributions | (Value - Mean) / StdDev | $\lvert Z\rvert > 3$ |
| **Modified Z-score (MAD)** | Distributions with outliers | 0.6745 × (Value - Median) / MAD | $\lvert \text{MAD-Z}\rvert > 3.5$ |

Table 26 – continued

| Method | Best For | Implementation | Threshold Example |
|---|---|---|---|
| **Percentile-based** | Unknown distributions, robust needs | Value at extreme percentiles | <1st or >99th percentile |
| **IQR method** | Box-plot style, non-parametric | Q1 - 1.5×IQR, Q3 + 1.5×IQR | Outside fences |
| **Isolation Forest** | Multivariate, complex patterns | Machine learning model | Anomaly score > 0.6 |

**Correction strategies**: **Flag and review** (preferred for sentiment indices—outliers may be genuine extremes); **Winsorize** (cap at threshold); **Remove and interpolate** (only if clearly erroneous) (IDEAS/RePEc) .

#### 2.3.3 Timestamp Synchronization Across Sources

**Timestamp standardization approach**:

1. **Record in UTC** at millisecond precision for all events
2. **Preserve original timezone** and local timestamp as metadata
3. **Align to market close** for daily data: 4:00 PM ET for US equities, respective local closes for other markets
4. **Handle daylight saving transitions** explicitly: flag ambiguous hours, use prevailing time
5. **Document any timestamp adjustments** in calculation methodology

**Synchronization validation**: Cross-check closing prices from multiple sources; verify options settlement times match equity closes; alert on timestamp mismatches >1 minute (The Conference Board) .

---

## Phase 3: Component Calculation Engine

### 3.1 Raw Indicator Computation

#### 3.1.1 Implement Momentum Calculations (125-Day ROC, SMA Distance)

```python
import pandas as pd
import numpy as np

class MomentumCalculator:
    def __init__(self, prices: pd.Series):
        self.prices = prices

    def rate_of_change(self, lookback: int = 125) -> pd.Series:
        """Calculate percentage change over lookback periods."""
        return (self.prices / self.prices.shift(lookback) - 1) * 100

    def sma_distance(self, lookback: int = 125) -> pd.Series:
        """Calculate percentage distance from simple moving average."""
        sma = self.prices.rolling(window=lookback).mean()
        return (self.prices / sma - 1) * 100
```

```python
    def normalized_momentum_score(self, roc: pd.Series,
                                  historical_roc: pd.Series) -> pd.Series:
        """Normalize ROC to 0-100 scale based on historical distribution."""
        # Use percentile ranking with sigmoid transformation for extremes
        from scipy.stats import percentileofscore

        def to_percentile(x, hist):
            if pd.isna(x):
                return np.nan
            p = percentileofscore(hist.dropna(), x, kind='rank')
            return p  # 0-100 scale

        scores = roc.apply(lambda x: to_percentile(x, historical_roc))
        return scores
```

(xjtlu.edu.cn)

### 3.1.2 Build Strength Metrics (52-Week High/Low Ratios)

```python
class StrengthCalculator:
    def __init__(self, price_df: pd.DataFrame):  # columns: tickers, index: dates
        self.prices = price_df

    def new_highs_lows(self, lookback: int = 252) -> pd.DataFrame:
        """Calculate new highs and lows for each date."""
        rolling_max = self.prices.rolling(window=lookback).max()
        rolling_min = self.prices.rolling(window=lookback).min()

        new_highs = (self.prices == rolling_max).sum(axis=1)
        new_lows = (self.prices == rolling_min).sum(axis=1)

        return pd.DataFrame({
            'new_highs': new_highs,
            'new_lows': new_lows,
            'total_active': self.prices.count(axis=1)
        })

    def high_low_ratio(self, hl_data: pd.DataFrame) -> pd.Series:
        """Calculate ratio of new highs to total extremes."""
        total_extremes = hl_data['new_highs'] + hl_data['new_lows']
        return (hl_data['new_highs'] / total_extremes * 100).where(total_extremes > 0)
```

### 3.1.3 Develop Breadth Measures (Advance-Decline Volume)

```python
class BreadthCalculator:
    def __init__(self, price_df: pd.DataFrame, volume_df: pd.DataFrame):
        self.prices = price_df
        self.volumes = volume_df

    def advance_decline_volume(self) -> pd.Series:
        """Calculate volume-weighted advance-decline."""
```

```
        price_change = self.prices.diff()

        up_volume = (self.volumes * (price_change > 0)).sum(axis=1)
        down_volume = (self.volumes * (price_change < 0)).sum(axis=1)

        # Handle division by zero
        ratio = np.where(
            down_volume > 0,
            up_volume / down_volume,
            np.where(up_volume > 0, np.inf, 1.0)
        )

        # Transform to 0-100 scale: log ratio centered at 50
        log_ratio = np.log(ratio.replace([np.inf, -np.inf], np.nan))
        # Normalize based on historical distribution...
        return self._normalize_to_100(log_ratio)

    def mcclellan_oscillator(self, ema_fast: int = 19,
                             ema_slow: int = 39) -> pd.Series:
        """Calculate McClellan Oscillator from net advances."""
        advances = (self.prices.diff() > 0).sum(axis=1)
        declines = (self.prices.diff() < 0).sum(axis=1)
        net_advances = advances - declines

        ema_19 = net_advances.ewm(span=ema_fast, adjust=False).mean()
        ema_39 = net_advances.ewm(span=ema_slow, adjust=False).mean()

        return ema_19 - ema_39
```

### 3.1.4 Integrate Volatility Feed (VIX or Realized Vol)

```
class VolatilityCalculator:
    def __init__(self, prices: pd.Series = None, vix_series: pd.Series = None):
        self.prices = prices
        self.vix = vix_series

    def realized_volatility(self, lookback: int = 21,
                            annualize: bool = True) -> pd.Series:
        """Calculate annualized realized volatility from returns."""
        returns = np.log(self.prices / self.prices.shift(1))
        vol = returns.rolling(window=lookback).std()

        if annualize:
            vol *= np.sqrt(252)

        return vol

    def vix_sentiment(self, vix_ma_lookback: int = 50) -> pd.Series:
        """Convert VIX to sentiment score (inverted, normalized)."""
        vix_ma = self.vix.rolling(window=vix_ma_lookback).mean()
        vix_ratio = self.vix / vix_ma
```

```
        # Invert: high VIX = low sentiment (fear)
        # Normalize based on historical distribution of ratio
        inverted = 1 / vix_ratio  # or more sophisticated transformation

        return self._normalize_to_100(inverted, invert=True)
```

### 3.1.5 Construct Options Sentiment Tracker (Put/Call Ratio)

```
class OptionsSentimentCalculator:
    def __init__(self, options_volume: pd.DataFrame):
        # DataFrame with columns: date, put_volume, call_volume
        self.options = options_volume

    def put_call_ratio(self, smoothing: int = 5) -> pd.Series:
        """Calculate smoothed put/call ratio."""
        pcr = self.options['put_volume'] / self.options['call_volume']
        return pcr.rolling(window=smoothing).mean()

    def pcr_sentiment(self, historical_pcr: pd.Series) -> pd.Series:
        """Convert P/C ratio to sentiment score."""
        # Invert: high P/C = fear (low sentiment)
        # Use percentile ranking for normalization
        current_pcr = self.put_call_ratio()

        def pcr_to_sentiment(pcr, hist):
            """Map P/C ratio to 0-100 sentiment (inverted)."""
            percentile = percentileofscore(hist.dropna(), pcr, kind='rank')
            # Invert: high P/C (high percentile) = low sentiment
            return 100 - percentile

        return current_pcr.apply(lambda x: pcr_to_sentiment(x, historical_pcr))
```

### 3.1.6 Implement Credit Spread Monitor

```
class CreditSpreadCalculator:
    def __init__(self, hy_yields: pd.Series, treasury_yields: pd.Series,
                 durations_match: bool = True):
        self.hy = hy_yields
        self.treasury = treasury_yields
        self.durations_match = durations_match

    def credit_spread(self) -> pd.Series:
        """Calculate high-yield credit spread."""
        if not self.durations_match:
            # Apply duration adjustment if needed
            pass
        return self.hy - self.treasury

    def spread_sentiment(self, historical_spreads: pd.Series) -> pd.Series:
        """Convert spread to sentiment (inverted: wide spread = fear)."""
```

```
        current_spread = self.credit_spread()

        # Wider spreads = lower sentiment
        # Use percentile ranking, with inversion
        def spread_to_sentiment(spread, hist):
            percentile = percentileofscore(hist.dropna(), spread, kind='rank')
            return 100 - percentile  # Invert: high spread = low sentiment

        return current_spread.apply(lambda x: spread_to_sentiment(x, historical_spreads))
```

### 3.1.7 Build Safe Haven Demand Comparator

```
class SafeHavenCalculator:
    def __init__(self, equity_returns: pd.Series, bond_returns: pd.Series):
        self.equity = equity_returns
        self.bonds = bond_returns

    def equity_bond_differential(self, lookback: int = 20) -> pd.Series:
        """Calculate rolling return differential."""
        equity_roll = self.equity.rolling(window=lookback).sum()
        bond_roll = self.bonds.rolling(window=lookback).sum()
        return equity_roll - bond_roll

    def safe_haven_sentiment(self, historical_diff: pd.Series) -> pd.Series:
        """Convert differential to sentiment score."""
        current_diff = self.equity_bond_differential()

        # Positive differential (equity outperformance) = greed
        # Negative differential (bond outperformance) = fear
        return self._normalize_to_100(current_diff,
                                      historical_range=(historical_diff.min(),
                                                        historical_diff.max()))
```

## 3.2 Normalization Module

### 3.2.1 Establish Historical Baselines for Each Component

**Baseline establishment procedure**:

1. **Collect minimum 10 years of historical data** for each component
2. **Calculate full distribution statistics**: mean, median, standard deviation, skewness, kurtosis, percentiles (1, 5, 10, 25, 50, 75, 90, 95, 99)
3. **Identify structural breaks**: Regime changes, policy shifts, market structure evolution
4. **Determine stable periods** for baseline calculation, or implement regime-dependent baselines
5. **Document baseline parameters** with effective dates and revision history
6. **Implement automated monitoring** for baseline drift requiring recalculation

(RavenPack)

### 3.2.2 Implement Min-Max Scaling Functions

```
class Normalizer:
    def __init__(self, method: str = 'min_max',
```

```
                 bounds: tuple = (0, 100),
                 handle_outliers: str = 'clip'):
        self.method = method
        self.bounds = bounds
        self.handle_outliers = handle_outliers

    def fit(self, historical_data: pd.Series):
        """Learn normalization parameters from historical data."""
        if self.method == 'min_max':
            self.min_val = historical_data.quantile(0.01)  # 1st percentile
            self.max_val = historical_data.quantile(0.99)  # 99th percentile
        elif self.method == 'z_score':
            self.mean = historical_data.mean()
            self.std = historical_data.std()
        elif self.method == 'percentile':
            self.historical = historical_data.dropna().values
        return self

    def transform(self, values: pd.Series, invert: bool = False) -> pd.Series:
        """Apply normalization to new values."""
        if self.method == 'min_max':
            scaled = (values - self.min_val) / (self.max_val - self.min_val)
            scaled = scaled * (self.bounds[1] - self.bounds[0]) + self.bounds[0]

            if self.handle_outliers == 'clip':
                scaled = scaled.clip(self.bounds[0], self.bounds[1])

        elif self.method == 'z_score':
            z = (values - self.mean) / self.std
            # Convert to 0-100 via sigmoid or CDF
            from scipy.stats import norm
            scaled = norm.cdf(z) * 100

        elif self.method == 'percentile':
            from scipy.stats import percentileofscore
            scaled = values.apply(
                lambda x: percentileofscore(self.historical, x, kind='rank')
            )

        if invert:
            scaled = self.bounds[1] - scaled + self.bounds[0]

        return scaled
```

### 3.2.3 Create Adaptive Boundary Detection (Rolling Percentiles)

```
class AdaptiveNormalizer(Normalizer):
    def __init__(self, window: int = 252 * 3,  # 3 years
                 update_frequency: int = 21,   # Monthly updates
                 **kwargs):
        super().__init__(**kwargs)
```

```
        self.window = window
        self.update_frequency = update_frequency
        self.last_update = None

    def update_if_needed(self, current_date, full_history: pd.Series):
        """Update baseline parameters on schedule."""
        if (self.last_update is None or
            (current_date - self.last_update).days >= self.update_frequency):
            recent_history = full_history.last(f'{self.window}D')
            self.fit(recent_history)
            self.last_update = current_date
            return True  # Updated
        return False  # No update needed
```

### 3.2.4 Handle Edge Cases (All-Zero or Saturated Inputs)

| Edge Case | Detection | Handling Strategy |
|---|---|---|
| **All identical values** | StdDev = 0, or all values equal min/max | Return neutral (50) or previous valid value; flag for review |
| **All zero/NaN input** | Count valid < threshold | Halt calculation, use last valid, or interpolate; alert operations |
| **Value beyond historical extremes** | < min or > max in fit data | Clip to bounds with flag, or extrapolate with caution |
| **Extreme outlier ( >5 )** | Z-score > 5 | Winsorize, flag, or require manual review depending on context |
| **Missing history for new component** | Insufficient data for fit | Use proxy, shorten lookback, or delay component inclusion |

(Quantified Strategies)

## 3.3 Weighting and Aggregation System

### 3.3.1 Code Equal-Weighting Engine

```
class EqualWeightAggregator:
    def __init__(self, components: List[str]):
        self.components = components
        self.n = len(components)
        self.weights = {c: 1.0 / self.n for c in components}

    def aggregate(self, component_scores: pd.DataFrame) -> pd.Series:
        """Calculate weighted average of component scores."""
        # component_scores: DataFrame with columns = component names
        weighted = component_scores.mul(self.weights)
        return weighted.sum(axis=1)

    def get_weights(self) -> Dict[str, float]:
        return self.weights.copy()
```

### 3.3.2 Implement User-Defined Custom Weights

```python
class CustomWeightAggregator(EqualWeightAggregator):
    def __init__(self, weights: Dict[str, float]):
        # Validate weights sum to 1.0
        total = sum(weights.values())
        if not 0.99 <= total <= 1.01:
            raise ValueError(f"Weights must sum to 1.0, got {total}")
        self.components = list(weights.keys())
        self.weights = {k: v / total for k, v in weights.items()}  # Normalize

    def update_weights(self, new_weights: Dict[str, float]):
        """Allow dynamic weight updates with validation."""
        self.__init__(new_weights)  # Re-validate
```

### 3.3.3 Develop PCA-Based Dynamic Weighting (Optional Advanced Feature)

```python
from sklearn.decomposition import PCA

class PCADynamicWeightAggregator:
    def __init__(self, n_components: int = 1,
                 lookback: int = 252,
                 update_frequency: int = 63):
        self.n_components = n_components
        self.lookback = lookback
        self.update_frequency = update_frequency
        self.pca = PCA(n_components=n_components)
        self.last_update = None
        self.current_weights = None

    def fit(self, component_history: pd.DataFrame):
        """Learn PCA weights from historical component data."""
        # Standardize before PCA
        from sklearn.preprocessing import StandardScaler
        scaler = StandardScaler()
        scaled = scaler.fit_transform(component_history.dropna())

        self.pca.fit(scaled)

        # First principal component loadings as weights
        loadings = self.pca.components_[0]

        # Convert to positive weights summing to 1
        # (Handle sign ambiguity: assume positive = greed direction)
        loadings = np.abs(loadings)
        self.current_weights = loadings / loadings.sum()

        self.component_names = component_history.columns.tolist()
        self.last_update = component_history.index[-1]

        return self
```

```python
    def aggregate(self, component_scores: pd.DataFrame) -> pd.Series:
        """Aggregate using PCA-derived weights."""
        if self.current_weights is None:
            raise RuntimeError("Must fit before transform")

        weights = dict(zip(self.component_names, self.current_weights))
        weighted = component_scores.mul(weights)
        return weighted.sum(axis=1)
```

### 3.3.4 Build Ensemble Combination Methods

```python
class EnsembleAggregator:
    def __init__(self, aggregators: List[Tuple[str, object, float]],
                 combination_method: str = 'average'):
        """
        aggregators: list of (name, aggregator_instance, weight_in_ensemble)
        combination_method: 'average', 'median', 'weighted', 'vote'
        """
        self.aggregators = aggregators
        self.combination_method = combination_method

    def aggregate(self, component_scores: pd.DataFrame) -> pd.Series:
        """Combine multiple aggregation methods."""
        results = []
        for name, agg, weight in self.aggregators:
            result = agg.aggregate(component_scores)
            results.append((name, result, weight))

        if self.combination_method == 'average':
            # Simple average of all methods
            return pd.concat([r[1] for r in results], axis=1).mean(axis=1)

        elif self.combination_method == 'weighted':
            # Weighted by ensemble weights
            weighted_sum = sum(r[1] * r[2] for r in results)
            total_weight = sum(r[2] for r in results)
            return weighted_sum / total_weight

        elif self.combination_method == 'median':
            # Median across methods (robust to outliers)
            return pd.concat([r[1] for r in results], axis=1).median(axis=1)

        elif self.combination_method == 'vote':
            # Majority vote on zone classification
            zones = pd.concat([self._to_zone(r[1]) for r in results], axis=1)
            return zones.mode(axis=1)[0]  # Most common zone
```

## Phase 4: Index Construction and Validation

### 4.1 Core Index Calculation

#### 4.1.1 Implement Weighted Average Aggregation

```python
class SentimentIndex:
    def __init__(self,
                 components: Dict[str, Callable],
                 aggregator: object,
                 smoothing: Optional[Tuple[str, int]] = None):
        """
        components: dict of component_name -> calculator_function
        aggregator: weighting and aggregation object
        smoothing: (method, period) e.g., ('sma', 5) or ('ema', 10)
        """
        self.components = components
        self.aggregator = aggregator
        self.smoothing = smoothing

    def calculate(self, data: Dict[str, pd.DataFrame]) -> pd.Series:
        """Calculate full sentiment index from raw data."""
        # Calculate each component
        component_scores = pd.DataFrame(index=data['prices'].index)

        for name, calculator in self.components.items():
            component_scores[name] = calculator(data)

        # Aggregate
        raw_index = self.aggregator.aggregate(component_scores)

        # Apply smoothing if specified
        if self.smoothing:
            method, period = self.smoothing
            if method == 'sma':
                index = raw_index.rolling(window=period).mean()
            elif method == 'ema':
                index = raw_index.ewm(span=period, adjust=False).mean()
        else:
            index = raw_index

        # Ensure bounds
        return index.clip(0, 100)

    def get_component_contributions(self) -> pd.DataFrame:
        """Return breakdown of how each component contributes to index."""
        # Implementation for drill-down visualization
        pass
```

#### 4.1.2 Add Smoothing Filters (Optional SMA/EMA) Smoothing decision framework:

| Smoothing | Effect | Best For | Risk |
|---|---|---|---|
| **None** | Maximum responsiveness, highest noise | High-frequency trading, algorithmic execution | False signals, whipsaws |
| **5-day SMA** | Moderate smoothing, slight lag reduction | Tactical trading, daily decision support | Some noise, minor lag |
| **10-day EMA** | Stronger smoothing, trend emphasis | Swing trading, weekly positioning | Significant lag at turns |
| **21-day SMA** | Monthly smoothing, major trend focus | Strategic allocation, regime identification | Late signals, missed opportunities |

**Recommendation**: **5-day SMA or 10-day EMA for most implementations**; unsmoothed only with specific high-frequency requirements; longer smoothing for strategic applications (supertype.ai) .

#### 4.1.3 Create Historical Backfill for Full Time Series

**Backfill procedure**:

1. **Establish earliest valid date**: Maximum of component data availability, minimum history for lookback calculations
2. **Sequential calculation**: Walk forward through history, using only information available at each date
3. **Handle evolving components**: If components added/removed, document and implement transition rules
4. **Validate against known events**: Verify index behavior during major market events matches expectations
5. **Publish with version metadata**: Track methodology changes, allow historical comparison

### 4.2 Validation Framework

#### 4.2.1 Correlation Analysis with Market Returns

```
class IndexValidator:
    def __init__(self, sentiment_index: pd.Series,
                 market_returns: pd.Series):
        self.index = sentiment_index
        self.returns = market_returns

    def correlation_analysis(self, horizons: List[int] = [1, 5, 21, 63, 252]):
        """Analyze correlation between sentiment and future returns."""
        results = {}

        for h in horizons:
            future_returns = self.returns.shift(-h)  # Future returns
            corr = self.index.corr(future_returns)

            # Rank correlation (Spearman) for non-linear relationships
            from scipy.stats import spearmanr
            rank_corr, _ = spearmanr(self.index.dropna(),
                                     future_returns.dropna())
```

```
            results[h] = {
                'pearson': corr,
                'spearman': rank_corr,
                'r_squared': corr ** 2
            }

        return pd.DataFrame(results).T

    def zone_performance(self, zones: pd.Series = None):
        """Analyze returns by sentiment zone."""
        if zones is None:
            zones = pd.cut(self.index,
                           bins=[0, 25, 50, 75, 100],
                           labels=['Extreme Fear', 'Fear', 'Greed', 'Extreme Greed'])

        return self.returns.groupby(zones).agg(['mean', 'std', 'count'])
```

#### 4.2.2 Regime Identification Accuracy Testing

**Regime identification evaluation**:

| Test | Method | Success Criteria |
|---|---|---|
| **Crisis detection** | Did index reach extreme fear before/during known crises? | Extreme fear within 1 month of crisis start in 80%+ of major events |
| **Bubble identification** | Did index reach extreme greed before known bubbles burst? | Extreme greed within 3 months of peak in 70%+ of bubble episodes |
| **Turning point timing** | How close to actual market turns did extremes occur? | Median absolute error < 10% of cycle duration |
| **False positive rate** | How often did extremes not lead to expected reversals? | <30% of extreme readings without significant reversal within 6 months |

(Personal Finance & Money Stack Exchange)

#### 4.2.3 Signal Timing and Lag Analysis

**Timing metrics to calculate**:

- **Lead time**: How many days/weeks before market turn did signal occur?
- **Lag time**: How long after signal did market respond?
- **Persistence**: How long did signal remain valid?
- **Decay**: How did predictive power diminish over time?

**Visualization**: Scatter plot of sentiment extreme dates vs. subsequent market turn dates; distribution of lead/lag times; survival curve of signal validity.

#### 4.2.4 Stress Testing Against Known Market Crises

| Crisis Period | Expected Index Behavior | Validation Criteria |
|---|---|---|
| **Oct 1987 Crash** | Rapid spike to extreme fear | >90 within 1 week of crash |

Table 30 – continued

| Crisis Period | Expected Index Behavior | Validation Criteria |
|---|---|---|
| **2000 Dot-com peak** | Extended extreme greed, then rapid fear | >75 for 3+ months before peak, <25 within 2 months of bottom |
| **2008 Financial Crisis** | Sustained extreme fear with periodic spikes | <25 for 6+ months, multiple <10 readings |
| **2020 COVID Crash** | Record-speed fear spike, V-shaped recovery | <10 within 2 weeks of bottom, rapid return to neutral |
| **2021 Meme Stock/ Crypto Mania** | Extreme greed in speculative assets | >75 with narrowing breadth, divergence from fundamentals |

*Table 18: Historical Stress Test Scenarios*

### 4.3 Threshold Calibration

#### 4.3.1 Historical Distribution Analysis

**Distribution analysis procedure**:

1. **Calculate full historical index distribution**: histogram, kernel density, percentiles
2. **Identify natural clusters**: Use statistical methods (k-means, Gaussian mixture) to identify data-driven zone boundaries
3. **Compare to theoretical expectations**: Should extreme zones be symmetric? Empirically, fear extremes often more pronounced
4. **Analyze zone durations**: How long does index typically remain in each zone?
5. **Correlate with subsequent returns**: Optimal thresholds maximize return differentiation between zones

#### 4.3.2 Quantile-Based Boundary Setting

| Zone | Default Quantile Range | Rationale | Adjustment Consideration |
|---|---|---|---|
| Extreme Fear | 0-10th percentile | Genuine panic, maximum opportunity | Lower bound may need floor (e.g., minimum score 0) |
| Fear | 10th-40th percentile | Elevated concern, defensive positioning | Wider range reflects fear persistence |
| Neutral | 40th-60th percentile | Balanced, no clear bias | Narrow range as neutral is transient |
| Greed | 60th-90th percentile | Optimism, risk-taking | Symmetric to fear range |
| Extreme Greed | 90th-100th percentile | Euphoria, maximum risk | Upper bound may need ceiling |

(8figures.com)

#### 4.3.3 User-Configurable Alert Levels

**Configuration options**:

```python
class AlertConfiguration:
    def __init__(self):
        self.thresholds = {
            'extreme_fear_entry': 25,   # Buy signal
            'fear_entry': 40,           # Start accumulating
            'neutral_upper': 60,        # Reduce momentum exposure
            'greed_exit': 75,           # Start taking profits
            'extreme_greed_exit': 90    # Maximum defensive position
        }
        self.hysteresis = 5  # Require 5-point move to change zone

        # Notification preferences
        self.channels = ['email', 'dashboard']
        self.cooldown_hours = 24  # Minimum between same-zone alerts

    def check_alerts(self, current_value: float, previous_value: float,
                     current_zone: str, previous_zone: str) -> List[dict]:
        """Generate alerts based on threshold crossings."""
        alerts = []

        # Zone change alerts
        if current_zone != previous_zone:
            alerts.append({
                'type': 'zone_change',
                'from': previous_zone,
                'to': current_zone,
                'value': current_value,
                'priority': self._zone_priority(current_zone)
            })

        # Threshold approach alerts (within hysteresis of next zone)
        # ... implementation

        return alerts
```

---

## Phase 5: Production Deployment

### 5.1 Automation and Scheduling

#### 5.1.1 Cron Job or Cloud Function Setup **Scheduling options by update frequency**:

| Frequency | Cron Expression | Cloud Alternative | Trigger Mechanism |
|---|---|---|---|
| Real-time | N/A (continuous) | AWS Lambda + EventBridge, Google Cloud Functions + Pub/Sub | Market data stream |
| Hourly | `0 * * * *` | Cloud Scheduler → Cloud Function | Time-based |
| 4x daily | `0 0,6,12,18 * * *` | Same | Time-based |

Table 32 – continued

| Frequency | Cron Expression | Cloud Alternative | Trigger Mechanism |
|---|---|---|---|
| Daily (market close) | `30 16 * * 1-5` (4:30 PM ET, weekdays) | Same | Time-based with market calendar |
| Weekly | `0 18 * * 5` (Friday 6 PM) | Same | Time-based |

**Implementation example (Google Cloud)**:

```yaml
# cloudbuild.yaml for Cloud Function deployment
steps:
  - name: 'gcr.io/cloud-builders/gcloud'
    args:
      - functions
      - deploy
      - sentiment_index_calculation
      - --runtime=python311
      - --trigger-topic=daily_market_close
      - --entry-point=calculate_index
      - --memory=512MB
      - --timeout=300s
      - --set-env-vars=DB_CONNECTION_STRING=$_DB_CONN,DATA_API_KEY=$_API_KEY
```

(marketgrader.com)

### 5.1.2 Error Handling and Retry Logic

**Error classification and response**:

| Error Type | Examples | Immediate Action | Retry Strategy | Escalation |
|---|---|---|---|---|
| **Transient data** | API timeout, rate limit | Log, use cached/stale data | Exponential backoff: 1, 2, 4, 8 min | After 4 retries, alert ops |
| **Data quality** | Outlier detected, missing field | Flag, use interpolation or halt | Manual review required | Immediate alert to data team |
| **Calculation** | Division by zero, invalid input | Use last valid, halt if persistent | N/A —requires code fix | Alert engineering |
| **Infrastructure** | Database connection lost, OOM | Failover to backup, restart | Automatic restart with backoff | PagerDuty if unresolved |
| **External dependency** | Market data feed down | Switch to backup source | Every 5 min source health check | Alert if both sources fail |

### 5.1.3 Logging and Monitoring Implementation

**Required logging levels**:

| Level | Events | Retention | Action |
|---|---|---|---|
| **DEBUG** | Detailed calculation steps, data points | 7 days | Development troubleshooting |

Table 34 – continued

| Level | Events | Retention | Action |
|---|---|---|---|
| **INFO** | Index calculation completed, normal operations | 30 days | Operational visibility |
| **WARNING** | Data quality issues, fallback usage, near-threshold performance | 90 days | Proactive monitoring |
| **ERROR** | Calculation failures, data unavailability, exceptions | 1 year | Immediate investigation |
| **CRITICAL** | Complete system failure, data corruption, security incident | 7 years | PagerDuty, post-mortem required |

**Monitoring dashboards**: Real-time index value and components; calculation latency; data source health; error rates; user access patterns.

### 5.2 User Interface Development

#### 5.2.1 Real-Time Gauge/Score Display

**Gauge design specifications**:

- **Primary display**: Large numerical score (0-100) with color gradient (red=0, yellow=50, green=100, or red-yellow-green-red for fear-neutral-greed-extreme greed)
- **Zone indicator**: Text label ("Extreme Fear", "Fear", "Neutral", "Greed", "Extreme Greed") with icon
- **Trend arrow**: Direction and magnitude of recent change
- **Timestamp**: Last update time with freshness indicator
- **Comparison**: Current vs. 1 week ago, 1 month ago, 1 year ago

**Technology stack**: D3.js or Chart.js for web; React Native or Flutter for mobile; matplotlib or plotly for research notebooks.

#### 5.2.2 Historical Chart Visualization

**Required chart types**:

| Chart | Purpose | Interactivity |
|---|---|---|
| **Time series line** | Index history with zone shading | Zoom, pan, event annotations |
| **Area chart with components** | Stacked contribution of each component | Toggle components on/off, hover for values |
| **Histogram** | Distribution of index values | Filter by date range, compare periods |
| **Scatter plot** | Index vs. subsequent returns | Color by time, size by return magnitude |
| **Heatmap** | Index by month/year | Drill to daily, compare years |

#### 5.2.3 Component Breakdown Drill-Down

**Drill-down hierarchy**:

```
Index Score (0-100)
```

```
├── Market Momentum (0-100)
│   ├── 125-day ROC: raw value, historical percentile
│   └── SMA Distance: raw value, historical percentile
├── Market Strength (0-100)
│   ├── New Highs/Lows: counts, ratio, trend
│   └── % Above 200-day MA: percentage, historical context
├── Market Breadth (0-100)
│   ├── Volume-Weighted A/D: ratio, McClellan Oscillator
│   └── Advance-Decline Line: cumulative, recent change
├── Volatility (0-100)
│   ├── VIX Level: current, vs MA, percentile
│   └── Realized vs Implied: spread, historical context
├── Options Sentiment (0-100)
│   ├── Put/Call Ratio: current, smoothed, historical
│   └── Skew/SKEW: level, trend
├── Credit Spreads (0-100)
│   └── High-Yield Spread: level, vs historical, trend
└── Safe Haven Demand (0-100)
    └── Equity-Bond Differential: 20-day return spread
```

**5.2.4 Export and Reporting Features** **Export formats**: CSV (raw data), JSON (API integration), PDF (formatted reports), Excel (analysis workbook).

**Scheduled reports**: Daily summary email; weekly deep-dive with component analysis; monthly performance attribution; quarterly methodology review.

### 5.3 Alert and Integration Systems

**5.3.1 Threshold-Crossing Notifications** **Alert configuration UI**:

- Zone entry/exit selection (multi-select)
- Custom threshold values with validation
- Minimum duration in zone before alert (prevent noise)
- Quiet hours (e.g., no alerts 11 PM - 6 AM)
- Delivery channel preferences by alert type

**5.3.2 API Endpoint for External Systems** **REST API specification**:

| Endpoint | Method | Parameters | Response |
|---|---|---|---|
| `/index/current` | GET | `format` (json, csv) | Latest index value, components, timestamp |
| `/index/historical` | GET | `start`, `end`, `frequency` | Time series of index values |
| `/index/components` | GET | `date` (optional, default current) | All component raw and normalized values |
| `/alerts/subscribe` | POST | `thresholds`, `channels`, `credentials` | Subscription confirmation with ID |
| `/alerts/unsubscribe` | DELETE | `subscription_id` | Confirmation |

**Authentication**: API keys with rate limiting; OAuth 2.0 for user-specific data; webhook signatures for

verification.

#### 5.3.3 Trading System Integration Hooks

**Integration patterns**:

| Pattern | Mechanism | Use Case | Complexity |
|---|---|---|---|
| **Webhook** | HTTP POST on threshold crossing | Alert external systems, trigger manual review | Low |
| **Message queue** | Publish to Kafka/ RabbitMQ | Event-driven architecture, multiple consumers | Medium |
| **Database trigger** | Notification on INSERT/ UPDATE | Direct database integration, legacy systems | Medium |
| **FIX protocol** | Standard financial messaging | Direct trading system integration | High |
| **Custom API** | REST/gRPC endpoint polled by trading system | Flexible, modern architecture | Medium |

---

## Phase 6: Maintenance and Evolution

### 6.1 Ongoing Monitoring

#### 6.1.1 Data Source Health Checks

**Daily automated checks**:

- All primary data sources updated within expected window
- No anomalous values (outside 5  of historical) in raw data
- Cross-source validation passes for overlapping data
- API response times within SLA (<500ms for critical paths)
- No error rates exceeding threshold (<0.1% of requests)

**Weekly manual review**: Exception logs; user feedback; market event correlation analysis.

#### 6.1.2 Calculation Accuracy Audits

**Monthly audit procedure**:

1. **Recalculate sample periods** with reference implementation
2. **Compare to production values**: Identify and explain any discrepancies
3. **Review methodology changes**: Document rationale, backtest impact
4. **Validate thresholds**: Confirm zone boundaries still appropriate
5. **Sign-off**: Technical lead and business owner approval

#### 6.1.3 Performance Benchmarking

**Key performance indicators**:

| KPI | Target | Measurement |
|---|---|---|
| **Calculation latency** | <5 seconds from market close | End-to-end timing logs |
| **API response time** | <200ms p95 | Application performance monitoring |

Table 38 – continued

| KPI | Target | Measurement |
|---|---|---|
| **Uptime** | 99.9% | Infrastructure monitoring |
| **Data freshness** | <15 minutes from source update | Timestamp comparison |
| **User satisfaction** | >4.0/5.0 | Quarterly survey |

### 6.2 Model Refinement

**6.2.1 Component Relevance Review** **Annual review questions**:

- Does each component still contribute unique information?
- Have any components become redundant due to correlation increase?
- Are there new data sources that could improve sentiment capture?
- Have market structure changes affected component interpretation?

**6.2.2 Weight Optimization Backtests** **Backtest protocol for weight changes**:

1. **Hypothesis**: Specific weight adjustment rationale
2. **In-sample optimization**: Grid search or optimization on training period
3. **Out-of-sample validation**: Test on holdout period not used in optimization
4. **Cross-market validation**: Test on related markets (e.g., if developed for S&P 500, test on NASDAQ, international indices)
5. **Paper trading**: Forward test with real-time data before production
6. **Gradual rollout**: A/B test with subset of users

**6.2.3 New Data Source Evaluation** **Evaluation criteria for new sources**:

| Criterion | Weight | Assessment Method |
|---|---|---|
| Theoretical relevance | 20% | Does it capture unique sentiment dimension? |
| Empirical predictive power | 25% | Backtest correlation with future returns |
| Data quality | 20% | Completeness, accuracy, timeliness validation |
| Cost-effectiveness | 15% | $ per incremental information unit |
| Implementation effort | 15% | Engineering time, infrastructure requirements |
| Regulatory/compliance | 5% | Licensing, usage restrictions, audit requirements |

### 6.3 Documentation and Training

**6.3.1 Technical Documentation Maintenance** **Required documentation**:

| Document | Update Frequency | Contents |
|---|---|---|
| **Architecture overview** | Major changes | System diagram, data flows, technology stack |
| **Calculation methodology** | Component changes | Formulas, parameters, normalization procedures |
| **API reference** | API changes | Endpoints, parameters, examples, error codes |

Table 40 – continued

| Document | Update Frequency | Contents |
|---|---|---|
| **Operations runbook** | Procedure changes | Deployment, monitoring, incident response |
| **Data dictionary** | Schema changes | Field definitions, sources, quality notes |

**6.3.2 User Guide Updates** **User documentation types**:

- **Quick start**: 5-minute setup for new users
- **Feature guide**: Detailed explanation of each capability
- **Interpretation guide**: How to read and act on sentiment signals
- **FAQ**: Common questions and troubleshooting
- **Release notes**: Changes in each version

**6.3.3 Knowledge Transfer Protocols** **Critical person risk mitigation**:

- **Code documentation**: Inline comments, docstrings, README files
- **Pair programming**: Regular rotation of developers across components
- **Incident post-mortems**: Shared learning, documented outcomes
- **Cross-training**: Multiple team members proficient in each area
- **Runbook exercises**: Regular drills of emergency procedures

---

## Appendix: Sample Python Implementation Structure

### A.1 Core Calculation Module

#### A.1.1 Data Retrieval Functions

```python
# data_retrieval.py
from abc import ABC, abstractmethod
from typing import Optional, Dict, List
import pandas as pd
import requests
from dataclasses import dataclass

@dataclass
class DataSourceConfig:
    name: str
    base_url: str
    api_key: Optional[str] = None
    rate_limit_per_minute: int = 60
    timeout_seconds: int = 30

class DataSource(ABC):
    def __init__(self, config: DataSourceConfig):
        self.config = config
        self.session = requests.Session()
        if config.api_key:
```

```python
            self.session.headers.update({'Authorization': f'Bearer {config.api_key}'})

    @abstractmethod
    def fetch_prices(self, symbol: str, start: str, end: str) -> pd.Series:
        pass

    @abstractmethod
    def fetch_options_data(self, underlying: str, date: str) -> pd.DataFrame:
        pass

class YahooFinanceSource(DataSource):
    """Free source for prototyping and basic use."""
    def fetch_prices(self, symbol: str, start: str, end: str) -> pd.Series:
        import yfinance as yf
        ticker = yf.Ticker(symbol)
        hist = ticker.history(start=start, end=end)
        return hist['Close']

    # ... other implementations

class PolygonSource(DataSource):
    """Professional-grade source with comprehensive coverage."""
    def fetch_prices(self, symbol: str, start: str, end: str) -> pd.Series:
        url = f"{self.config.base_url}/v2/aggs/ticker/{symbol}/range/1/day/{start}/{end}"
        response = self.session.get(url, params={'apiKey': self.config.api_key})
        data = response.json()
        # Parse to pandas Series...
        pass
```

### A.1.2 Normalization Utilities

```python
# normalization.py
import numpy as np
import pandas as pd
from scipy.stats import percentileofscore, norm
from typing import Union, Optional, Tuple
from enum import Enum

class NormalizationMethod(Enum):
    MIN_MAX = 'min_max'
    Z_SCORE = 'z_score'
    PERCENTILE = 'percentile'
    SIGMOID = 'sigmoid'

class Normalizer:
    def __init__(self,
                 method: NormalizationMethod = NormalizationMethod.MIN_MAX,
                 bounds: Tuple[float, float] = (0, 100),
                 outlier_handling: str = 'clip'):
        self.method = method
        self.bounds = bounds
```

```python
        self.outlier_handling = outlier_handling
        self._fitted = False

    def fit(self, historical_data: pd.Series):
        """Learn normalization parameters from history."""
        clean = historical_data.dropna()

        if self.method == NormalizationMethod.MIN_MAX:
            # Use percentiles to reduce outlier impact
            self._min = clean.quantile(0.01)
            self._max = clean.quantile(0.99)

        elif self.method == NormalizationMethod.Z_SCORE:
            self._mean = clean.mean()
            self._std = clean.std()

        elif self.method == NormalizationMethod.PERCENTILE:
            self._historical = clean.values

        self._fitted = True
        return self

    def transform(self, values: Union[float, pd.Series],
                  invert: bool = False) -> Union[float, pd.Series]:
        """Apply normalization."""
        if not self._fitted:
            raise RuntimeError("Must fit before transform")

        if self.method == NormalizationMethod.MIN_MAX:
            scaled = (values - self._min) / (self._max - self._min)
            scaled = scaled * (self.bounds[1] - self.bounds[0]) + self.bounds[0]

            if self.outlier_handling == 'clip':
                scaled = np.clip(scaled, self.bounds[0], self.bounds[1])

        elif self.method == NormalizationMethod.Z_SCORE:
            z = (values - self._mean) / self._std
            # Convert to 0-100 via CDF
            scaled = norm.cdf(z) * 100

        elif self.method == NormalizationMethod.PERCENTILE:
            if isinstance(values, pd.Series):
                scaled = values.apply(lambda x: percentileofscore(self._historical, x))
            else:
                scaled = percentileofscore(self._historical, values)

        else:
            return 'Extreme Greed'
```

## A.2 Visualization Components

### A.2.1 Time-Series Plotting

```python
# visualization.py
import plotly.graph_objects as go
from plotly.subplots import make_subplots

class SentimentIndexChart:
    def __init__(self, index_data: pd.DataFrame):
        self.data = index_data

    def create_main_chart(self) -> go.Figure:
        fig = make_subplots(rows=2, cols=1,
                            shared_xaxes=True,
                            vertical_spacing=0.05,
```

```
                        row_heights=[0.7, 0.3])

    # Main index line with zone shading
    fig.add_trace(
        go.Scatter(
            x=self.data.index,
            y=self.data['index_value'],
            name='Sentiment Index',
            line=dict(color='black', width=2),
            fill='tozeroy',
            fillcolor=self._zone_color_fill(self.data['index_value'])
        ),
        row=1, col=1
    )

    # Zone boundaries
    for level, color in [(25, 'red'), (50, 'gray'), (75, 'green')]:
        fig.add_hline(y=level, line_dash="dash",
                      line_color=color, opacity=0.5,
                      row=1, col=1)

    # Component contributions (stacked area)
    components = [c for c in self.data.columns if c.startswith('component_')]
    for comp in components:
        fig.add_trace(
            go.Scatter(
                x=self.data.index,
                y=self.data[comp],
                name=comp.replace('component_', ''),
                stackgroup='components'
            ),
            row=2, col=1
        )

                        {'label': '5 Years', 'value': '5Y'},
                        {'label': 'All', 'value': 'ALL'}
                    ],
                    value='1Y'
                ),
                dcc.Interval(id='auto-refresh', interval=60000)  # 1 minute
            ]),

            # Data table for detailed view
            html.Div(id='data-table')
        ])

    def _setup_callbacks(self):
        @self.app.callback(
            [Output('gauge-container', 'children'),
             Output('historical-chart', 'figure'),
             Output('component-chart', 'figure')],
            [Input('time-range', 'value'),
             Input('auto-refresh', 'n_intervals')]
        )
        def update_dashboard(time_range, _):
```

```python
            # Fetch latest data
            data = self.calculator.get_historical_data(time_range)

            # Create visualizations
            chart = SentimentIndexChart(data)

            return (
                dcc.Graph(figure=chart.create_gauge(data['index_value'].iloc[-1])),
                chart.create_main_chart(),
                chart.create_component_breakdown()
            )

    def run(self, debug=False, port=8050):
        self.app.run_server(debug=debug, port=port)
```

## A.3 Deployment Configuration

### A.3.1 Environment Setup

```python
# requirements.txt
pandas>=1.5.0
numpy>=1.23.0
scipy>=1.9.0
scikit-learn>=1.1.0
plotly>=5.10.0
dash>=2.6.0
requests>=2.28.0
yfinance>=0.1.87
python-dotenv>=0.20.0
pytest>=7.1.0
black>=22.6.0
flake8>=5.0.0
mypy>=0.971

# Optional for production
gunicorn>=20.1.0
redis>=4.3.0
celery>=5.2.0
```

```python
# setup.sh
#!/bin/bash
set -e

echo "Setting up Fear & Greed Index environment..."

# Create virtual environment
python3 -m venv venv
source venv/bin/activate

# Install dependencies
pip install --upgrade pip
```

```
pip install -r requirements.txt

# Create environment file
cat > .env << EOF
# Data API Keys (replace with actual values)
POLYGON_API_KEY=your_key_here
ALPACA_API_KEY=your_key_here
ALPACA_SECRET_KEY=your_secret_here

# Database
DATABASE_URL=postgresql://user:pass@localhost:5432/sentiment_index

# Application
UPDATE_FREQUENCY=daily
LOG_LEVEL=INFO
EOF

echo "Setup complete. Edit .env with your API keys."
```

### A.3.2 Dependency Management

**Dependency update protocol**:

1. **Pin major versions** in requirements.txt for reproducibility
2. **Monthly review** of security advisories for dependencies
3. **Quarterly updates** of non-critical dependencies with testing
4. **Annual major version upgrades** with full regression testing
5. **Automated CI/CD** testing on dependency updates

### A.3.3 Cloud Deployment Templates

**Dockerfile**:

```
# Dockerfile
FROM python:3.11-slim

WORKDIR /app

# Install system dependencies
RUN apt-get update && apt-get install -y \
    gcc \
    postgresql-client \
    && rm -rf /var/lib/apt/lists/*

# Install Python dependencies
COPY requirements.txt .
RUN pip install --no-cache-dir -r requirements.txt

# Copy application
COPY src/ ./src/
COPY config/ ./config/

# Set environment
ENV PYTHONPATH=/app/src
ENV PYTHONUNBUFFERED=1
```

```
# Run
CMD ["python", "-m", "src.main"]
```

**docker-compose.yml for local development**:

```yaml
version: '3.8'

services:
  app:
    build: .
    ports:
      - "8050:8050"
    environment:
      - DATABASE_URL=postgresql://postgres:postgres@db:5432/sentiment
      - UPDATE_FREQUENCY=daily
    depends_on:
      - db
      - redis
    volumes:
      - ./src:/app/src  # For development hot-reload

  db:
    image: timescale/timescaledb:latest-pg14
    environment:
      - POSTGRES_USER=postgres
      - POSTGRES_PASSWORD=postgres
      - POSTGRES_DB=sentiment
    volumes:
      - postgres_data:/var/lib/postgresql/data
    ports:
      - "5432:5432"

  redis:
    image: redis:7-alpine
    ports:
      - "6379:6379"

  scheduler:
    build: .
    command: celery -A src.scheduler worker -B --loglevel=info
    environment:
      - DATABASE_URL=postgresql://postgres:postgres@db:5432/sentiment
      - REDIS_URL=redis://redis:6379/0
    depends_on:
      - db
      - redis

volumes:
  postgres_data:
```

**Kubernetes deployment** (production):

```yaml
# k8s-deployment.yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: sentiment-index-api
spec:
  replicas: 3
  selector:
    matchLabels:
      app: sentiment-index-api
  template:
    metadata:
      labels:
        app: sentiment-index-api
    spec:
      containers:
      - name: api
        image: gcr.io/PROJECT/sentiment-index:latest
        ports:
        - containerPort: 8000
        env:
        - name: DATABASE_URL
          valueFrom:
            secretKeyRef:
              name: db-credentials
              key: url
        - name: POLYGON_API_KEY
          valueFrom:
            secretKeyRef:
              name: api-keys
              key: polygon
        resources:
          requests:
            memory: "512Mi"
            cpu: "500m"
          limits:
            memory: "1Gi"
            cpu: "1000m"
        livenessProbe:
          httpGet:
            path: /health
